OF THE

SOCIETY OF ARTS

VOLUME LV.

FROM NOVEMBER 23, 1906, TO NOVEMBER 15, 1907.

LONDON:

PUBLISHED FOR THE SOCIETY BY GEORGE BELL AND SONS,
YORK HOUSE, PORTUGAL STREET, LINCOLN'S INN FIELDS, W.C.

1907.

Journal of the Society of Arts.

No. 2,818. VOL. LV.

FRIDAY, NOVEMBER 23, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

ONE-HUNDRED-AND-FIFTY-THIRD SESSION, 1906-7.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One-hundred-and-Fifty-Third Session was held on Wednesday Evening, the 21st of November, when an Address was delivered by Sir STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

NOVEMBER 28.—JOHN WILLIAM GORDON, "Patent Law Reform." SIR WILLIAM H. PREECE, K.C.B., F.R.S., will preside.

DECEMBER 5.—COLONEL SIR CHARLES M. WATSON, K.C.M.G., C.B., "The Metric System." SIR DAVID GILL, K.C.B., F.R.S., will preside.

DECEMBER 12.—CECIL H. HOOPER, Member of the Council of the National Fruit-Growers' Asssociation, "Fruit Growing and the Protection of Birds."

" 19.—ALBERT E. HUMPHRIES, President of the Incorporated Association of British and Irish Millers, "Modern Developments of Flour-Milling." THOMAS HUDSON MIDDLETON, M.A., Professor of Agriculture, Cambridge University, will preside.

Papers to be read after Christmas:—

PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company, "The Straits of Panama."

THOMAS EMLEY YOUNG, B.A., Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association, "The Principles and Practice of Insurance, and their modern Develep ments."

JOHN B. C. KERSHAW, F.I.C., "Smoke Prevention in Factories."

CLAYTON BEADLE, "The Underground Water Supply of the Thames Basin."

J. CRAIG ANNAN, "Engraving and Photogravure."

NOEL HEATON, B.Sc., "Mediæval Stained Glass, its Production and Decay."

HAL WILLIAMS, "Cold Storage and Food Supply."

ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts, "Modern Typewriters and Accessories."

COLONIAL SECTION.

Tuesday Afternoons, at 4.30 o'clock:—

DECEMBER 4.—THE HON. SIR LEWIS LLOYD MICHELL, "The Cape to Cairo Railway." THE RIGHT HON. VISCOUNT MILNER, G.C.B., G.C.M.G., will preside.

January 15, March 5, May 7.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

DECEMBER 13.—A. YUSUF ALI, M.A., LL.M., Cantab, I.C.S., "The Indian Mohammedans: their Past, Present, and Future." LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

January 24, February 14, March 14, April 25, May 30.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

DECEMBER 18.—THOMAS OKEY, "Basket Making." LEWIS FOREMAN DAY, F.S.A., will preside.

January 29, February 19, March 19, April 30, May 28.

CANTOR LECTURES.

Monday evenings at 8 o'clock:—

A. D. HALL, M.A., Director of Lawes Agricultural Trust, "Artificial Fertilisers: their Nature and Functions." Five Lectures.

LECTURE I.—NOVEMBER 19.—*The Nutrition of the Plant.*—General principles of the nutrition of plants—Photosynthesis and the utilisation of solar energy—Nitrogen assimilation—The ash-constituents, necessary and non-necessary—The soil and its composition—Its power of supplying certain of the crop constituents but not all—The function of a fertiliser—History of the introduction of artificial fertilisers.

LECTURE II.—NOVEMBER 26.—*The Fixation of Nitrogen.*—The plant's dependence upon a supply of combined nitrogen—How has the general supply of combined nitrogen in the world arisen?—Inorganic agencies trifling—Action of bacteria, in symbiosis with leguminous plants, or free in the soil—Energetics of nitrogen fixation: source of energy in the combustion of carbohydrate formed by photo-synthesis—Attempts to increase the fixation by bacteria in the soil—Fixation of nitrogen as a manufacturing process—The calcium nitrate and nitric acid processes—Calcium cyanamide—Price dependent upon the cost of power—How far can the farmer render himself independent of nitrogen fertilisers?

LECTURE III.—DECEMBER 3. —*Nitrogenous Fertilisers.*—Nature, origin and preparation :—Sodium nitrate—Ammonium sulphate—Guanos—Waste products: Shoddies, oil seed residues, &c.—The bacterial process in the soil by which these materials are prepared for the plant—Statistics of their comparative activity and recovery by the crop—Function of nitrogen as a fertiliser.

LECTURE IV.—DECEMBER 10.—*Phosphatic Fertilisers.*—The requirements by soil and crop of phosphoric acid, its function as a fertiliser—Solubility of various phosphates—The utilisation of natural phosphates—Bones: various forms; source of supply—Superphosphate from mineral phosphates—Manufacture—Sources of the material—Basic slag as a waste product in the manufacture of steel by the Thomas-Gilchrist basic process—Its special value on certain types of land.

LECTURE V.—DECEMBER 17.—*Potassic Fertilisers. Consumption of Fertilisers.*—Potassic fertilisers, their function. Large store of potash in most soils—The Stassfurth potash deposits and the manufacture of potash manures therefrom—Examples of the value of potassic fertilisers—The part played by lime and calcium carbonate in the retention of fertilisers by the soil, and their utilisation by the plant—The farmer's fertiliser bill. Should it be increased?—Partly a question of prices, intensive farming only profitable when prices are high—Partly a question of education, if the manure now used were more carefully bought and more skilfully adjusted to soil and crop, the greater profit would justify an increased purchase.

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.
January 28; February 4, 11.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.
February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.
April 15, 22, 29.

JUVENILE LECTURES.

Wednesday Evenings, January 2 and 9, 1907, at 5 o'clock.
"Perils and Adventures Underground." By BENNETT H. BROUGH.

CONVERSAZIONE.

The Annual Conservazione of the Society will probably be held on Tuesday, July 2, 1907. Each member is entitled to a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

CHARTER.—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department or science in connection with the Arts, Manufactures, and Commerce of this country."

THE SESSION.—The Session commences in November, and ends in June.

ORDINARY MEETINGS.—At the Wednesday Evening Meetings during the Session, papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

COLONIAL SECTION.—The Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies. Four or more Meetings are held during the Session.

APPLIED ART SECTION.—This Section was formed in 1886, for the discussion of subjects connected with the industrial applications of the Fine Arts. Six or more Meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists of from two to six Lectures.

ADDITIONAL LECTURES.—Special Courses of Lectures are occasionally given.

JUVENILE LECTURES.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the Children of Members during the Christmas Holidays.

ADMISSION TO MEETINGS.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

JOURNAL OF THE SOCIETY OF ARTS.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

EXAMINATIONS.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education, and Music. Full particulars of the Examinations can be had on application to the Secretary.

LIBRARY AND READING-ROOM.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

CONVERSAZIONI are held, to which Members are invited, each Member receiving a card for himself and a lady.

MEMBERSHIP.

The Society numbers at present nearly four thousand Members. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

Every Member whose subscription is not in arrear is entitled .—

To be present at the Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admission to all Exhibitions held by the Society at its house in the Adelphi.

To be present at all the Society's *Conversazioni*.

To receive a copy of the weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

All subscriptions should be paid to the Secretary, Sir Henry Trueman Wood, and all Cheques or Post-office Orders should be crossed "Coutts and Company," and forwarded to him, at the Society's House, John-street, Adelphi, London, W.C.

HENRY TRUEMAN WOOD, *Secretary.*

CALENDAR FOR THE SESSION.

The Meetings of the Indian Section and the Colonial Section will commence at Half-past Four o'clock.

The Meetings of the Applied Art Section will commence at Half-past Four or Eight o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Five o'clock.

NOTICES.

H.M. THE KING OF NORWAY.

The Council of the Society having elected H.M. the King of Norway an Honorary Royal Member, H.R.H. the Prince of Wales, as President of the Society, graciously communicated to King Haakon the fact of his election, and has now received from His Majesty the following letter of acceptance :—

Windsor Castle,
November 15, 1906.

SIR,—In reply to your Royal Highness's letter, dated November, 1906, I beg to assure you that I shall have great pleasure in being enrolled an Honorary Royal Member of the Society of Arts.

I much value the compliment thus paid to me, and I shall be proud in being associated with an Institution so old and so distinguished, and over which your Royal Highness now presides.

I have the honour to be, Sir,
Your Royal Highness's most
faithful servant,
(Signed) HAAKON R.

To His Royal Highness
The Prince of Wales, K.G.

CANTOR LECTURES.

On Monday evening, 19th inst., Mr. A. D. HALL, M.A., Director of the Lawes Agricultural Trust, delivered the first lecture of his course on "Artificial Fertilisers : their Nature and Functions."

The lectures will be published in the *Journal* during the Christmas recess.

MORRIS'S CANTOR LECTURES ON INDIA RUBBER.

The Cantor Lectures of Sir Daniel Morris, K.C.M.G., on the "Plants yielding Commercial India Rubber" (1898), which have long been out of print, have now been reprinted, and are on sale at the price of two shillings each. The pamphlet can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 21st, 1906; SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council, in the chair.

The following members were proposed for election as members of the Society :—

Adams, Miss Katharine, Eadburgha Bindery, Broadway R.S.O., Worcestershire.
Addis, Frederick Henry, Assoc.M.Inst.C.E., B.B. and C.I. Railway, Mhow, Central India.
Akimoto, Viscount, 6 Kita Koga-cho, Surugadai, Tokyo, Japan.
Araki, Professor Kwampo, 3 Nishimachi, Shitaya, Tokyo, Japan.
Armstrong, Miss Carr, R.M.S., 76, Longridge-road-mansion, Earl's-court, S.W.
Asano, Sōichiro, 18, Kitashinbori-cho, Nihonbashi-ku, Tokyo, Japan.
Baillie, Mrs. A. H. Murray, 94, Eaton-place, S.W.
Baxter, Walter Stephen, 38, Mayflower-road, Clapham, S.W.
Beatson, E. B., Vicarsgrange, Eastbourne.
Bebianno, Domingos Alves, care of Mark Sutton, 130*a*, Rua Barão de Mesquita, Andarahy Grande, Rio de Janeiro, Brazil, South America.
Beech, Ernest William, 32, Lincoln-road, Peterborough.
Bisset, William Molteno, Colonial Mutual-buildings, Adderley-street, Cape Town, South Africa.
Blount, Lady E. A. M., F.R.S.L., 73, West-street, Brighton.
Bonner, Albert Edward, 18, Holland-street, Kensington, W.
Bonnor, John H. M., 10, Trafalgar Studios, Manresa-road, Chelsea, S.W.
Boright, Sherman H., Forbes Reef, Swazieland, South Africa.
Box, Eliab, 287-289, Broadway, Bexley-heath, Kent.
Brown, Miss Charlotte, 115, Gloucester-road, S.W.
Buck, James Henry Edward, A.M.I.Mech.E., P.O. Box 1,049, Johannesburg, Transvaal, South Africa.
Buckton, William Woodyer, B.A., 72, Victoria-street, S.W., and Royal Societies' Club, St. James's-street, S.W.
Bultitude, Henry Frank, 18, Philip-road, Peckham-rye, S.E.
Campbell, Richardson, Dunedin, Woodlands-street, Cheetham-hill, Manchester.
Carter, Major Evan E., C.M.G., M.V.O., Stanhope Lines, Aldershot.
Cartlidge, S. J., 9, Netherton-grove, Chelsea, S.W.
Chambers, James S., Kutais, Trans-Caucasus, and 5, Ionkovskafa, St. Petersburgh, Russia.
Chapin, Robert Williams, 28, Bishopsgate-street Within, E.C.
Choles, Major Frederick John, Ordnance Officer, Natal Militia, Pietermaritzburg, Natal, South Africa.

Chow, Taotai C. L., Imperial Railways of North China, Tientsin, China.

Clemens, Benjamin, 23, Fitzroy-square, W.

Collingwood, John James, Clovelly, Cecil-road, Upton Manor, E.

Cooper, J. Paul, The Elms, Castle Bromwich, Warwickshire.

Corkett, Frederic Thomas, 3, Redcliffe-gardens, Ilford, Essex.

Crocker, Ernest George, A.M.I.Mech.E., H.M. Naval Establishment, Rosyth, Fife, N.B.

Croll, James, Olaa Sugar Company, Limited, Olaa, Hawaii.

Cross, Reginald Thomas Green, A.M.I.Mech.E., Khoreel Tea Estate, Daloo P.O., Cachar, India.

Damania, Lieut.-Colonel P. J., Northbrook Society, 185, Piccadilly, W.

Davidson, Rev. William, The Manse, Chryston, by Glasgow.

Davies, James Bright, Northern Nigeria Enclave, Burutu, Southern Nigeria, West Africa.

Divecha, Ramchundra Nursey, A.M.I.Mech.E., Sugar-lane, Kaloopur Post, Ahmedabad, India.

Dixon, G. E., M.D., Heathfield, Chislehurst, Kent.

Dressler, Conrad, White-cottage, Marlow, Bucks.

Dyce, James S., Barberton, Transvaal, South Africa.

Eddy, Sidney Arthur, Carn Brea-house, Observatory, Cape Town, South Africa.

Emanuel, Frank L., 67, Ladbroke-grove, Kensington, W.

Etti, Captain Charles, M.A., The European Eastern Asia Trader Association, Limited, West India House, 98, Leadenhall-street, E.C.

Fisher, Henry Heibert, Calle Zapiola 2,075, Belgrano, Buenos Aires, Argentine Republic.

Fitton, Hedley, A.R.E., Stile-house, Haslemere, Surrey.

Flockhart, William, F.R.I.B.A., 180, New Bond-street, W.

Foley, J. E., Imperial Railways of North China, Tientsin, China.

Foster, Richard, M.A., J.P., D.L., Lanwithan, Lostwithiel, Cornwall.

Frankel, Alfred, Dunedin-house, Basinghall-avenue, E.C.

Fulton, Hon. Frederick John, K.C., Kamloops, British Columbia, Canada.

Garfield, Sergyei, "Ussuri Life" Office, Vladivostock, Siberia.

Gascoine, Edmund, Sir W. G. Armstrong, Whitworth and Co., Limited, 32, Great Peter-street, Westminster, S.W.

George, William Carlisle, Ecole Khédiviale d'Arts et Metiers, Cairo, Egypt.

Ghosh, Dr. Jogesh Chandra, L.M.S., L.C.P.S., College of Physicians and Surgeons, 3, Wellesley-street, Calcutta, India.

Gollin, Alfred, 561, Bourke-street, Melbourne, Victoria, Australia.

Gowen, Rev. Herbert H., Trinity Parish Church, Seattle, Washington, U.S.A.

Greenwell, Allan, F.G.S., Assoc.M.Inst.C.E., 30-31, Furnival-street, Holborn, E.C.

Hannon, Patrick Joseph Henry, Department of Agriculture, Capetown, South Africa.

Hartness, John A., Jones and Lamson Machine Company, 97, Queen Victoria-street, E.C.

Hartrick, Archibald Standish, 8, Wentworth Studios, Manresa-road, Chelsea, S.W.

Hatton, Major-General Villiers, C.B., 34, Charles-street, Berkeley-square, W.

Hodson, Arthur J., Lodore, Southborough-road, Chelmsford.

Hope, Charles E., Messrs. Hope, Graveley and Co., 322, Cambie-street, Vancouver, British Columbia, Canada.

How, William, 19, Calverley-park, Tunbridge Wells, Kent.

Inouyé, K., 54, Ichiban-chō Kojimachi, Tokyo, Japan.

Johnson, Hon. F. E. R., Monrovia, Liberia, West Africa.

Jones, George Edward, 25, Lexham-gardens, S.W.

Jones, William Henry Matthews, The Town-hall, Chester.

Keely, Royal R., City Engineer, Edmonton, Alberta, Canada.

Keen, Percy, 3 Queen's-mansions, Victoria-street, S.W.

Kimura, Professor Shunkichi, Ph.D., Naval Ordnance Depôt, Yokosuka, Sami, Japan.

King, Henry Douglas, 52, Queensborough-terrace, W.

Kitchin, Vernon Parry, B.A., The Priory, Watford, Herts.

Lal, Hira, 25, Mott's-lane, Calcutta, India.

Lavan, Lloyd Thomas, L.D.S., 12, Old Burlington-street, W.

Lawrie, Peter Stanley, Koe Guan Co., 63 Beach-street, Penang, Straits Settlements.

Le Mesurier, James, The United Asbestos Oriental Agency, Limited, Singapore, Straits Settlements.

Lesher, Arthur Lawrence, Messrs. Lesher, Whitman and Co., Broadway, corner of Bond-street, New York, U.S.A.

Lindsay, James G., City Engineer, Guelph, Ontario, Canada.

Low Kim Pong, 86, Market-street, Singapore, Straits Settlements.

Lynch, Captain C. W. D., care of London and Westminster Bank, St. James's-square, S.W., and Kasempa, North Western Rhodesia, South Africa.

McClean, John Robinson, Rusthall-house, Tunbridge Wells, Kent.

McDiarmid, James, Winnipeg, Manitoba, Canada.

Mackay, Francis Duncan, Messrs. Leighton and Mackay, 544, Bartholome Mitre, Buenos Aires, Argentine Republic.

Mackintosh, Mrs. E. R., 79, Lancaster-gate, W.

McNaughton, John L., Rosemount, Buckie, N.B.

MacWatt, Major Robert Charles, M.B., B.Sc., I.M.S., care of Messrs. King, King and Co., Bombay, India.

Mallins, Charles William, 5, Strathmore-road, Newsham-park, Liverpool.

Marks, Arnold J., 17, Lansdowne-place, Hove, Sussex, and 54 and 55, London-wall, E.C.

Maud, Captain William Hartley, Norton-manor, near Taunton, Somerset, and 57, Eaton-square, S.W.

Merrall, Charles Eddington, 20, Grove-lane, Denmark-hill, S.E.

Miles, Laurence, Rose-bank, Strawberry-vale, Twickenham, Middlesex.

Millar, Rev. Ernest, M.A., Mengo, Uganda, East Africa, and Heathdown, Hampstead-heath, N.W.

Millett, Charles Walter, Abbotsford, Hampton-wick, Middlesex.

Milner, George H., 15, Limes-grove, Lewisham, S.E.

Minihane, E. J., 5, Castelnau-row, Barnes, S.W.

Mitchell, Felix, 81, Burg-street, Cape Town, South Africa.

Mocatta, Owen, 31, Cumberland-place, Hyde-park, W., and Leyfield, Datchet, Berks.

Moore, Lieutenant A. Usborne, R.N., H.M.S. "Queen," care of General Post-office, E.C.

Mulla, Yusuf I., 28th Street, Rangoon, Burma.

Murphy, Edward Robert, Sports Club, 8, St. James's-square, S.W.

Nishizawa, Kimio, Dayeh Iron Mine Department, Hupeh, China.

Oberg, Gustaf Leonhard, Shanghai Mutual Telephone Company Limited, Shanghai, China.

O'Neil, Rodolph Stuart, 29, Bergholt-crescent, Amhurst-park, Stamford-hill, N.

Owen, Captain Roger Carmichael Robert, C.M.G., Sudan Agency, War Office, Cairo, Egypt, and Naval and Military Club, Piccadilly, W.

Owens, Felix I. A., A.M.I.E.E., 68-70, Wood-street, Liverpool.

Penning, Sydney Heathcote, 94, Griffin-road, Plumstead, S.E.

Petter, Ernest Willoughby, M.I.Mech.E., 1, Hill-side-mansions, Highgate, N.

Phené, John Samuel, LL.D., F.S.A., 32, Oakley-street, Chealsea, S.W.

Philipson-Stow, Robert, Blackdown-house, Fernhurst, Sussex.

Pibel, William Henry, The Roses, Salway-hill, Woodford-green, Essex.

Plimmer, Mrs. Bertha Helena, 3, Hall-road, N.W.

Plummer, J. H., care of Canadian Bank of Commerce, 60, Lombard-street, E.C., and Toronto, Canada.

Porter, Colonel Geoffrey Morehead, R.E., H.M. Mint, Calcutta, India.

Redwood, Bernard Boverton, B.A., 34, Crediton-road, South Hampstead, N.W.

Richardson, David Lester, 60, Allison-road, Hornsey, N.

Robertson, John, 54, St. James's-street, Piccadilly, S.W.

Roote, Gilbert J., 1260, O'Farrell-street, San Francisco, California, U.S.A.

Roselieb, George, 9, Grafton-square, Clapham, S.W.

Rosenkrantz, Baron Arild, 18, Clareville-grove, Onslow-gardens, S.W.

Rous, Bartholomew, 53, Madeley-road, Ealing, W.

Sait, Hajee Ismail, Bangalore, India.

Sawtell, William Arthur, 39, Deauville-road, Clapham-park, S.W.

Seymour, L. N., D.D.S., L.D.S., 27, Grosvenor-street, W.

Shozaburo, Kubara, Nichome Nakanoshima, Osaka, Japan.

Smith, Eric S. A., Messrs. Boulton and Paul, Limited, Norwich.

Smith, George R., M.L.A., Thetford Mines, Quebec, Canada.

Smith, T. L., 346, Camden-road, N.

Stevens, Wm. Henry Pern, 34, Ashburn-place, S.W.

Stuart, James, Assam Bengal Railway Company, Limited, Chittagong, India.

Tabor, Francis Samuel, District Judge, Rai Bareli, Oudh, India.

Taylor, Arthur Williamson, Edmonton, Alberta, Canada.

Tildesley, F. J., General Post Office, Johannesburg, Transvaal, South Africa.

Twentyman, Harold E., M.I.Mech.E., Stoneham lodge, Tettenhall, Wolverhampton.

Vaidya, Jain, Johari Bazaar, Jaipur, Rajputana, India.

Van Boeschoten, J. G., Reserve Investment-buildings (P.O. Box 611), Pretoria, Transvaal, South Africa.

Vereker, Lieutenant Henry Gosset, R.N., Coloony, Craneswater-avenue, Southsea, Hants.

Vernon, William, Wyborne-gate, Birkdale, Southport, Lancs.

Vidyabhusan, Pundit Gauridatta Misra, Gauhati, Assam, India.

Vogel, Dr. J. Ph., Superintendent, Archæological Survey, Lahore, India.

Walker, Robert Lea, 15, Park-crescent, Southport, Lancs.

Wehner, Anthony Stephen, Bath-house, 57, Holborn-viaduct, E.C.

Whitworth, G. Clifford, Crowhurst, College-road, Upper Norwood, S.E.

Wilkinson, Andrew George, 73, Dudley-gardens, West Ealing, W.

Wong Man Poh, 19, Market-street, Singapore, Straits Settlements.

Wood, David William, 4, St. Andrew's-mansions, Clapton, N.E.

Woodhouse, Richard, Bonegate-hall, Brighouse, Yorks.

Wright, Thomas George, 3, Purton-road, Bristol.

Wrightson, Miss Lucy G., Ockenden, Cuckfield, Sussex.

Young, Mrs. H. E., care of Dr. H. E. Young, M.P.P., Parliament-buildings, Victoria, British Columbia, and Atlin, British Columbia, Canada.

The CHAIRMAN delivered the following

ADDRESS.

Our ancestors had some singular tastes. They loved to hear sermons. Mr. G. Russell, in his latest book "Social Silhouettes," speaks of it as a "base passion of our fallen nature," and accuses the clergy of pandering to instead of opposing it; but though this is exaggeration, you have only to read Pepys's Diary to see how the writer, whose morality left somethihg to be desired, pursued sermons with no less earnestness than other and less reputable pleasures. More than that, when they could not get the professional thing, our ancestors went out of their way to listen to amateur imitations, and caused chairmen of meetings, and presidents of societies, and other innocent persons to deliver "addresses" to them. I think and hope that public taste is changing; but we are a very conservative people, and it is because of these two facts (1) that our ancestors liked sermons, and (2) that we dislike change, that I, whose tastes do not lie in that direction, have to deliver the usual annual address to you this evening. With us, however, it is something more than a matter of custom. There is a specific rule which calls for it — the by-law being to the effect that the Chairman of the Council shall deliver an address to the Society at its first ordinary meeting after his election declaratory of the policy which the Council proposes to follow during his year of office. Accordingly, I find that at one time the annual addresses, after dealing with the losses sustained by the Society during the year through the death of distinguished members, and giving a retrospect of the subjects dealt with at the meetings of the past year, would go on to touch on the questions which were to be the subjects of papers during the ensuing session, or which the Chairman would like to have brought before the notice of the Council, with a view to the influence of the Society being brought to bear upon the Government and the Parliament. I may mention that, at the time I am speaking of (thirty to forty years ago) this influence was, or at least was supposed to be, considerable, and was certainly exerted more directly by means of deputations and written communications to Ministers, and by questions in the House, than is the case at the present day. For instance, I find in the proceedings for one year (1869) the following instances :— A committee appointed to watch over the interests of telegraphy and promote the efficiency of the system, owing to the Government taking over the management. The Council asked by the Secretary of State for India to obtain information on behalf of the Indian Government on the processes of cleaning and husking rice in Europe. The Colonial Office consult the Council on the subject of meat preserving. A special deputation sent to the Duke of Argyll to urge the appointment of a Minister of Agriculture for India, and that he should assist agricultural exhibitions in that country. Council invite the Prime Minister to facilitate the circulation by loan of art treasures. Council to bring pressure to bear on Government to lighten the postage rate on printed matter. While questions such as the above occupied the attention of the Council, it was not unreasonable that the Chairman should be expected to propound the policy of the coming year. How or when this practice changed I have not ascertained, but it seems as if the discussion of the Council's past and present policy tended naturally to become little more than a *resumé* of the previous year's annual report and a forecast of the papers for the ensuing year, and that consequently successive chairmen, most of whom have been specialists in some particular line, have found it more to the interest and advantage of their audience to discuss some interesting question connected with their own professional or personal specialty, rather than to adhere to the strict letter of the by-law; to give, in fact, a "paper," rather than the annual address on policy.

Now, for me the duty of following in the footsteps of my distinguished predecessors is hard. The only subject on which I can claim any special knowledge is that of India, and I should naturally have wished to take as the subject of my address the arts, manufactures, and commerce of India, but I find that when Major-General Sir Owen Tudor Burne was Chairman of the Council a few years ago he took this as the theme of his discourse and went so fully into it as to leave nothing but gleanings! Indeed he left not even gleanings. He covered the whole field and that with a reaping machine not a sickle. Goldsmith's epitaph applies to him in both its clauses.

Moreover in the subsequent years the Society has had very valuable papers on different aspects of the subject from Mr. Tozer and Mr. O'Conor, and on looking into the question I found that I could only say over again what had been better said before especially by my predecessor in the chair, Major-General Sir Owen Tudor Burne.

"Pereant qui ante nos nostra dixerunt." Bad luck to the men who appropriate our subjects by anticipation. But the fact remains that they have been appropriated and I have had to look elsewhere for a subject on which I might hope to interest you to-night. The subject I have chosen is the Indian Section of the Society of Arts, and I hope to interest you in it because I have taken a great interest in it myself, and if other members of the Society, besides those specially connected with India, can be induced to take interest in it, it still has I think great scope for usefulness in the future.

The Indian Section, or as it was at first called the Indian Committee, had its origin in a motion made in January, 1869, by Mr. Hyde Clarke. Mr. Hyde Clarke, who died in 1895, was, for many years, an active and useful member of the Society and its Council. A full obituary notice of him will be found in the March number of the Society's *Journal* for that year. An engineer by profession, he appears to have had no special connection with India, beyond being asked to advise on a telegraph system for that country. But he was a man of many original ideas, and of untiring energy in pushing his suggestions. The Society certainly owes to him the establishment of the Indian and Colonial Sections—the latter having been originally designated the African Section—as well as many other useful suggestions in connection with the Society's work.

As a consequence of Mr. Hyde Clarke's motion, there appeared in the *Journal* for January 29th, 1869, the following notice :—

COMMITTEE ON INDIA.

The Council have resolved that a Committee be formed "to organise meetings for the discussion of subjects connected with the Arts, Manufactures, and Commerce of our Indian Empire."

The following gentlemen have been already invited to serve on this Committee :—

Archibald Campbell.	C. H. Fielder.
George Campbell.	W. S. Fitzwilliam.
Edwin Chadwick, C.B., Member of Council of Society of Arts.	George Moffatt.
Hyde Clarke, Member of Council of Society of Arts.	Sir Robert Montgomery, K.C.B., Vice-President of the Society of Arts.
Sir Daniel Cooper, Bart., Member of Council of Society of Arts.	Colonel Sykes, M.P.
Sir William Denison.	Captain Edward Thackeray.
Maj.-Gen. Sir Vincent Eyre, C.B., Member of Council of Society of Arts.	Sir Charles Trevelyan, K.C.B.
	Dr. J. Forbes Watson.

In addition to these gentlemen, the East Indi Association has been requested to nominate three of its members to join the Committee.

The Secretary of the Society of Arts will be glad to receive the names of any members of the Society taking an interest in Indian questions, in order that they may be invited to attend the meetings above referred to.

The Committee met on 16th February, with Sir Vincent Eyre in the chair. Those who know the history of the Indian Mutiny will remember the brilliant services of Eyre in the relief of Arrah and the dispersal of the Dinapore mutineers. The other members were Sir William Denison, late Governor of Madras, Dr. Archibald Campbell, the companion of Dr. Hooker's scientific journeys in Sikkim, and late District Officer of Darjeeling, Mr. Fielder, Secretary of the Tea Association, and Mr. Hyde Clarke.

These gentlemen proposed that six conferences should be held during the session on various subjects, specially on Tea, Waste Lands, and Trade with Border States. They also suggested a large list of names of gentlemen to be asked to join the Committee. The list is interesting, and shows a notable combination of names conspicuous in the Indian world of the day, such as Sir Bartle Frere, Sir G. Campbell, Sir Ranald Martin, Sir R. Montgomery, Sir Henry Rawlinson, and Dr. Forbes Watson, with names conspicuous in the English world, such as Dr. Chadwick, Sir C. Wentworth Dilke, James Fergusson, the archæologist, Sir Macdonald Stephenson, and Sir Digby Wyatt.

The first conference, as it was called, was held on March 12th, 1869, with Dr. A. Campbell in the chair. The proceedings were prefaced by a few remarks from Mr. Hyde Clarke, showing the objects of the Council in calling the Indian Committee into existence. He said—

"That they were aware that the Society of Arts had devoted itself from an early period to the promotion of Arts, Manufactures, and Commerce, not only in connection with this country, but with our colonies and with India. From time to time various subjects connected with India has been brought before this Society, and those subjects had always been received with attention ; it was natural, therefore, that those gentlemen who were specially interested in such matters, should apply to the Society of Arts to appoint a committee with a view to the holding of discussions on various Indian questions, because these subjects came within its domain, and it was equally natural that the Council, in its desire to promote a public

object of great importance, should accede to the request. It was under these circumstances these meetings had been projected. It had been the desire of the India Committee that these meetings should be in the nature of conferences, in order to elicit a greater variety of opinion, the subject to be considered being introduced by a short paper. He might congratulate them upon the presence this evening of many gentlemen greatly interested in India."

A paper on "Tea Cultivation" was then read by Mr. Fielder, the Secretary of the Tea Association, who gave its history from the first discovery of the tea plant in Assam by Dr. Bruce (to whom this Society gave its gold medal), through the period of its early fostering by Government, who, after four or five years pioneer work, made over their experimental gardens, in 1840, to the Assam Tea Company, up to the date of the lecture, a period of thirty years, when the export of Indian tea was something over 8 million lbs. It is now about 212 million lbs.

In June, 1869, the Committee reported that they had held six conferences, with four additional meetings for adjourned discussions, and made various suggestions to the Council, including the offer of a medal for the best essay on tea cultivation, and that the Council should move the Government of India to establish a department of agriculture, with the object of diffusing information and encouraging the production and amelioration of various agricultural staples. They added that, in view of the success that had attended the first year's conferences, and the number of important subjects still demanding their attention, they recommended the continuance of the Committee's action. This latter suggestion was acceded to, and I gather from an allusion made to the subject in the annual address of the Chairman (Lord Henry Lennox), delivered in November, 1869, that the advice of the Committee on the former subject was also adopted. He said that "one result of these conferences was that a deputation waited on the Duke of Argyll, and pressed on his Grace the importance of developing the agricultural resources of India by the appointment of a Minister of Agriculture, and by extending the system of assisted exhibitions of agricultural produce in India. The Duke of Argyll received the deputation with great cordiality, &c." It was shortly after this—*post hoc*, if not *propter hoc*—that the Agricultural Department of the Government of India was formed — a department which, after a starved infancy, owing both to want of means as well as want of knowledge, has of late years done much useful work, but only recently under Lord Curzon's administration has received a fairly efficient scientific equipment and may be expected to do much more in the future than it has done in the past.

How the Indian Committee of these early years came to blossom into the Indian Section is not on record, but in 1874 when other "Sections" of the Society were formed the name of Indian Section was substituted for that of Indian Committee.

Passing over a succession of years of useful work I come to some noteworthy proposals made in 1875 bearing on the use and functions of the Indian Section.

On January 29th, 1875, Sir G. Campbell delivered a remarkable address to the Indian Section of the Society of Arts at the opening of the Session. Sir George Campbell had recently returned from the post of Lieut.-Governor of Bengal. He was a man whose really remarkable ability and mental energy were lost sight of and rendered useless by his habit of addressing the House of Commons on every subject that came under discussion whether within or without the scope of his experience or knowledge. Nature, moreover, while endowing him with this inordinate love of speaking, had at the same time handicapped him with a voice and manner which rendered the task of listening to him singularly irritating, so that as a member of the House of Commons his reputation was not what his friends would have wished. Yet he was a man of real intellectual power, with a passion for absorbing information, had written several good books about India, and as Lieutenant-Governor of Bengal gave a progressive impulse to the Government of that province, which, if it rather disturbed for the time the conservative traditions of his colleagues and subordinates, has proved the fruitful parent of most of the larger reforms worked out in subsequent administrations. Returning from his work as Lieutenant-Governor, he was full of the difficulties and obstacles that had lain in the way of the reforms and improvements he was in a hurry to introduce. He explained that whereas in England all improvements in Arts, Manufactures, and Commerce came from private enterprise; in India, it was necessary that the Government should lend a hand in starting such improvements, but that in trying to introduce any technical teaching, he had found that there was no machinery. Government officials had not the requisite knowledge of the subject,

and English experts had not the requisite knowledge of Indian conditions, nor had he, as Lieutenant-Governor, a sufficient backing of public interest to overcome the *vis inertiæ* of the administrative machine. He thought he might find in the Indian Section of this Society, the machinery by which, to some extent, the necessary knowledge might be imparted, and the requisite motive power might be obtained to remove or minimise these difficulties.

"It seems clear," he said, "that there is room for great effort and great improvement, and for that improvement I think the Government of India must very much rely upon the aid of a Society constituted as this Society is—a Society devoted, I think I may say, to material as distinguished from moral and legal improvement, a Society which has taken upon itself to advance material improvement in all its branches of Arts, Manufactures, and Commerce, and which has been good enough to establish an Indian Section, in the hope that by its means a great deal may be done in regard to the progress of India.

"An immense field lies before the Society in this respect, and I think it offers a theatre in which real improvement may be practically developed to a very great extent. We know that in this country there are a very large number of practical men interested in India from a commercial and industrial point of view. On the other hand, there are resident in this country a large number of men thoroughly experienced in Indian administration; men possessing a great deal of leisure, a great deal of knowledge, and a great deal of practical experience and influence; and I believe that the function of this Society is to bring together these old Indians, and the commercial and industrial representatives of this country, in order that they may work together for the material improvement of that great country, which has been committed to our hands, and in which we have so great an interest."

Accordingly, he laid before the Society a portentous list of subjects for discussion, enough to fill a dozen sessions. Their mere outline will give you an idea of the extent of his ambition. Agriculture generally, cattle breeding, irrigation and drainage, and the sanitation connected therewith — all these were to be considered. Cotton, jute, fibres, silk, sugar, tobacco, all these had a future before them, if this Society would only show how their cultivation and manufacture might be improved. Then we were to throw light on the best policy for dealing with waste lands and with labour for the tea districts. We were to develop forestry, rubber, and cinchona plantations. Indigo (alas for human foresight!) was the one crop in which he thought Europeans had made a permanent success in India, and he was jubilant over it at the very time when friends of the planters were trying to induce them to combine for the introduction of scientific teaching both for the growth and manufacture of it. Now that it is too late this is being done and the Government are assisting liberally; had it been tried thirty years ago a great industry, and one of no less political than commercial value, might have avoided ruin. From vegetable products he turned to minerals. Iron and coal were found together. There should be a great iron industry in India. In their arts we might at least improve not the design but the material of Indian pottery. In their manufactures the Indians were already learning their lesson and setting up mills to compete ultimately with those of Manchester and Dundee. Finally, the Society should consider the needs of India in regard to communications, railways (the controversy between the broad gauge and metre gauge was in his mind), roads, lighthouses and harbours.

Sir G. Campbell was more explicit in finding subjects for discussion than in explaining how such discussion would influence the Government of India and assist in bringing about the reforms which he advocated, though in the passage I have already quoted he shows that the combination of Indian experience with scientific and commercial eminence to be found among the members of this Society would not fail to exert a beneficial influence when brought to bear on the Government and the public. At the end of his address he makes a more explicit recommendation.

"I do hope," he says, "That not only we may bring together much experience in this room for the great benefit of both countries, but I also believe it is quite possible, by developing these subjects and creating an interest in them here, you may create a corresponding interest in India also. I know of no problem in respect to India which is more interesting than that of turning into a useful channel the immense amount of education and development that we are now bringing out amongst the native classes of India. We are at this moment educating very highly large numbers of young men of the most intelligent classes in India. . . . You must turn that education into useful material channels; and amongst these young men themselves and amongst the native population I think there is a very considerable disposition to accept this view—that it is absoluteiy necessary that a large proportion ot their educated men should learn to rival Europeans, not only in respect to intellect, but in respect to practical art; and I do hope that if these subjects are earnestly taken up by this Society, we shall find that

we shall have in the great towns in India affiliated societies which will take them up on that side of the water also, which will correspond with us and learn from us, and that so working together the societies in India and this parent Society in this country may really effect very material improvement, both directly in the condition of the people in India, and indirectly by affording a field in which the education which we are now supplying to the natives may be turned into a useful channel."

Here we have a definite suggestion for extending the utility of the Indian Section, by having affiliated branches of the Society in India, and though this part of Sir G. Campbell's programme has never been carried out, and is to my mind of doubtful utility, the idea has been worked, not unsuccessfully, elsewhere. In other respects, I may say that the methods laid down in the early days of the Committee's existence, and even Sir George Campbell's extensive programme have been followed with conscientious fidelity, and have led to some evolutionary development. I have been making an analysis of the papers read before the Indian Section from the beginning, and without inflicting on you the whole of it, I may mention that seven of them deal with the tea industry; silk and cotton, and other fibres, claim twelve. Sir G. Campbell's optimistic views about indigo seem to have pervaded the Section, for I only find one paper devoted to it, and that when the ruin of the once flourishing industry was already well nigh accomplished. Railways have had no less than fourteen meetings given up to them, and a similar number have been devoted to agriculture, though this question has been dealt with more often from the revenue side than in a purely scientific aspect. The manufactures, the mineral resources, the external commerce, the currency of India and its irrigation have all received an equivalent share of attention, each subject having occupied the attention of the Section for eight evenings. But, as I have said, there has been much fresh ground broken up besides and beyond that originally contemplated by the committee. Some of the most iuteresting papers read before the Section have been those on the wilder tribes within or contiguous to the Indian frontier. Of these we have had sixteen and a similar number dealing with Afghanistan and Persia. Lately, moreover, the committee of the section have endeavoured, with considerable success, to provide a series of papers dealing in turn with each province and presidency town. Of these there have been twelve given, and I hope the series will be rendered complete. Other subjects have engaged much attention. Famines, the census, domestic life, architecture, sanitation, all these have been considered, and treated with more or less adequacy, and a vast amount of valuable information on them made available to the public. I should have expected the subject of education to have attracted more attention, especially that of female education, where the Society might have given valuable assistance, but in all I find only three evenings devoted to it. In addition to what I have enumerated above there have of course been a number of single papers upon special subjects, some of them such as Dr. Grierson's brilliant paper on the linguistic survey of India, of the highest possible value but not coming under any of the above categories. Then the question arises not only as to the quantity but as to the quality of these papers. We want to know who are the teachers as well as what are the subjects taught. Well, with very few exceptions, I may say that the writers of these papers have been acknowledged experts on the subjects treated of and in many cases the leading experts. The early years give us papers by such honoured names as Sir Arthur Cotton, Sir Bartle Frere, Sir George Birdwood (why does he no longer assist us with his papers ?), Sir Joseph Fayrer, Professor Vambery, Sir Richard Temple, Sir Caspar Purdon Clarke, Dr. Leitner, and many others. In later days, we have the "Economic Resources of India" dealt with by Sir G. Watt, the author of the "Economic Dictionary of India." We have the late Sir William Hunter lecturing on the "Religions of India." Forests are dealt with by Dr. Schlich; Burmah, by ("Shway Yeo") Sir J. G. Scott; Kafristan, by Sir G. Robertson Scott; Seistan, by Sir Henry Macmahon; Chitral, by Sir F. Younghusband—all these, at the time, were the recognised leading authorities on these special subjects. The same may be said of the papers given us by Sir Frederic Goldsmid, Sir Thomas Holdich and Major Molesworth Sykes on subjects connected with Persia. In regard to less specialised subjects, I need not remind you of the many brilliant papers we have had from the present Chairman of the Indian Section, Sir William Lee-Warner, from Sir C. Elliott, Sir Athelstane Baines, and many others. I should like to name very many more, but I think I have proved my point that these papers,

dealing with Indian subjects, and specially calculated to direct attention to them, and impart information concerning them, are the work, not of casual or ill-informed persons desirous of notoriety, or with axes of their own to grind, but of the men recognised in their own walks of life, as being the most solidly informed, and the most worth listening to on their own special subjects. Then the next question to be asked is, How far have these papers excited public interest and attained the object with which the Section was instituted? To this question it is obvious that a direct reply can hardly be given. We can only gather indications of the importance which may be attached to them outside. I think I may say from my own experience that they attract as large and influential audiences as those ordinarily attending the meetings of other sections of the Society, and that they are followed by discussions which display vivid interest and creditable knowledge, and which are almost always closured by the time limit and not brought to an end from exhaustion. Then as another test, let us see who are the people willing to come and preside at them. We have had as chairmen during the years of my own connection with the Committee (to go no further back), Lord Roberts, the late Lord Northbrook, Lord Elgin, Lord Curzon (three times), Lord G. Hamilton (on six occasions) Earl Spencer, Lord James of Hereford, the late Lord Russell, of Killowen, Mr. Brodrick, and the late Sir Henry Stanley. These are not men who would have cared to lend their time and support to wholly useless or even trivial meetings. Then we may ask, have we a hearing among our Indian fellow-subjects? Well, at different times, six of them — the earliest, Mr. Dadabhai Naorojee (in 1871), Professor J. C. Bose (in 1897), and the latest Mr. Wagle (in 1902)—have themselves occupied the platform, and we are promised, I am glad to say, another paper in December by a Mahommedan gentleman, Mr. Yusuf Ali. Among the members of the Society, there are some 250 residing in India, of whom half probably are Europeans. But among Indian names we have the Maharajas of Jodhpore, of Travencore, of Bhawnagur, of Kuch Behar, of Burdwan, and of Bobili. Indian commerce, too, is very strongly represented—and among retired Anglo-Indians we have enough ex-Viceroys, Governors, Lieutenant - Governors, Members of Council, &c., to furnish a complete, if somewhat mixed, administration—at all events, we have enough here to show that the proceedings of the Section are not without interest, and if occasion required, might not be without influence.

I should not like to let this opportunity go by without saying publicly how much the Indian Section is indebted for its success in recent years to the work of its able and energetic Secretary, Mr. Digby, especially in the matter of obtaining (by peaceful persuasion!) the admirable papers to which I have alluded from our modest or unenterprising contributors, and then bringing them to the notice of all persons likely to be interested; and it is in our large and attentive audiences that he finds his work has not been in vain.

I have often given consideration to the question how—outside the slow process of educating public opinion by papers and discussions, the process of infiltration which is always going on—the Indian Section of this Society may be further developed and made more fruitful, but I cannot say that I have any useful suggestion to offer. I have shown that in early days gone by the Society used to bring direct pressure to bear on the Government by means of deputations and correspondence. I can imagine that in exceptional circumstances it would still be possible to adopt such a course, and a sufficient array of influential names both commercial and official might be collected to justify it. But the circumstances would have to be very exceptional, and we must never forget that as a rule this Society rigidly eschews party politics, and day by day every subject on which we might wish to influence the Government tends more and more to become a question of party politics. Apart from this method of acquiring influence, the only suggestion I have seen is that of having affiliated branches of the Society in India. The subject is worth considering, and might well be made the subject of a paper at some future meeting of the Society. Personally I see little to be gained by it, and serious pitfalls in the way of it, and I should hesitate to advocate it. Then it is to be noticed that there are other societies whose aims and objects are to some extent identical with, or at least overlap, those of the Indian Section. Now the history of the Society of Arts, as has been shown in the Address of one of its recent Chairmen, has been that of fissiparous reproduction, that is to say, different sections having grown to maturity, have broken off from the parent society and formed separate specialised asso-

ciations. It may ultimately be the fate of the Indian Section to do this, and amalgamate with other similar societies, into one large Indian association, but, at present, I see no probability of this—the time for it, if it ever comes, is not yet. The Indian Section has neither the wish nor the capacity to set up house on its own account, and break off from the parent society—and I only mention the suggestion to discountenance it. But, on the other hand, I should welcome a time when the Indian Section of the Society of Arts might absorb the other societies; when, in a building with ample accommodation, the Section might be allowed its own office, library and meeting-room, as a centre of information on Indian subjects. But, perhaps, this, too, is for the present, Utopian.

On the whole then, reviewing the past, I think the Indian Section has had a fairly useful and successful life, and I can suggest nothing better than to go on as we are going, *super antiquas vias*, and let time bring its own development. Even as it is the man who has studied the weekly *Journal* of the Society of Arts has provided himself with a liberal education. In this way we may augur for it a long life of continued and increasing usefulness.

I have referred in the earlier part of my Address to the by-law which makes it incumbent on the Chairman to refer to the lines on which the Council propose to carry on work during the ensuing session. A few words, therefore, on our prospects may not be deemed inappropriate.

The list of papers to be read at the Ordinary Meetings is a very full one, and I think promises as interesting session as any we have had. There will be four meetings before Christmas, at the first of which Mr. J. W. Gordon is to read a paper on "Patent Law Reform," a subject which has always been of the greatest interest to the Society. Another topic which has often been dealt with in this room will be treated by Sir Charles Watson on the following Wednesday, namely, "The Metric System." Most previous papers have been in advocacy of the system, but I understand that Sir Charles Watson will deal principally with the practical objections to its introduction. The results of the over-protection of birds on the fruit-growing industry has been a cause of frequent complaints this summer, and this topic will be treated by Mr. Cecil Hooper, who is himself interested as a practical fruit-grower. At the other meeting before Christmas the President of the Association of Millers, Mr. Albert Humphries, will tell us something about recent improvements in Flour Milling and the production of Bread.

We have already a number of papers arranged for the meetings after Christmas, one of which on the Panama Canal is of special interest, because the author is the distinguished French engineer who was formerly in control of the work, Monsieur Bunau-Varilla. Lord Montagu, of Beaulieu, has, I am glad to say, promised us a paper on "Motor Omnibuses," which certainly ought to lead to a good discussion. Another paper likely to be of value is one by Mr. E. Young on "Life Insurance," and there are also many others of considerable interest.

There will be one meeting of the Indian Section before Christmas, at which a paper is to be read by Mr. A. Yusuf Ali on the "Indian Mohammedans," and one also of the Colonial Section, when Sir Lewis Michell will discuss "The Cape to Cairo Railway." In the Applied Art Section, Mr. Thomas Okey will describe the history and art of "Basket Making."

Other papers promised or in contemplation for the Indian Section are on the practical working of famine relief—personal reminiscences by Sir Frederic Lely, lately Chief Commissioner of the Central Provinces; a paper on the City of Madras, in pursuance of the series to which I have already alluded, by Sir James Thomson, late Member of the Madras Council; one on the "Irrigation Colonies of Sind and the Punjab," and one on the employment in India of the Italian method of utilising river silt for the production of fertile land, by Sir Edward Buck.

In the Colonial Section we hope to have papers after Christmas on "The Progress of the Uganda Protectorate," by Mr. G. Wilson, C.B., Deputy Commissioner; "on British Malaya," by Sir W. H. Treacher, and on "Rubber Cultivation in the British Empire," by a well-known expert.

In the Applied Art Section after Christmas, papers are promised on the "Artistic Treatment of the Exterior of the Pianoforte," by Mr. William Dale, and on "Joinery and Cabinet Making," by Mr. A. Romney Green. Mr. A. P. Laurie, Principal of the Heriot Watt College, Edinburgh, will continue the discussion of the important subject of the Materials used in the painting of pictures, which Professor John M. Thomson treated last session in his paper on the "Chemistry of Artists' Colours." Mr. Laurie will deal with

"Oils, Varnishes, and Mediums." Mr. Sherard Cowper-Coles will contribute a paper on "Sheffield and Electro-plate."

The Cantor Lectures, I am glad to think, are well up to the standard of these valuable communications. Mr. A. D. Hall has already commenced his course on "Artificial Fertilisers." You know how much attention has been drawn of late to this subject. Sir William Crookes prophecies the ultimate failure of our wheat crops if we are obliged to depend for the supply of nitrates which the soil requires on existing sources, and says the only hope of the agriculturist is in the fixation of nitrogen from the atmosphere. That the fixation of atmospheric nitrogen on a commercial scale is possible has been shown by more than one inventor, but whether or no it can be produced at a sufficiently low cost yet remains to be demonstrated. The courses after Christmas will deal with Gold Mining, Romanesque Ornament, and the Materials used in Laundry Work—a sufficiently varied list.

One word more. I have hinted in dealing with the future of the Indian Section that we are somewhat cramped for space. For the past two years, the Council were not without hopes that the Society might have received a great extension by becoming amalgamated with the London Institution, and that a new Society might have been established to carry on the work of these ancient Institutions with renewed vigour. As you are aware, the efforts made in this direction have come to nothing. But the Council are now endeavouring to ascertain whether additional accommodation cannot be provided for the Society on the site it has so long occupied, by the acquisition of adjacent premises. Whether this can be successfully accomplished, and on terms which the Society can afford, is a question which is now engaging their very careful attention, and should their endeavours be successful, I have no doubt that the Indian Section no less than the Society at large will be greatly benefited.

After delivering the Address the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings :—

To Mr. W. F. MITCHELL, for his paper on "The Commerce and Industries of Japan."

To Dr. WILLIAM ARTHUR AIKIN, for his paper on "The Scientific Aspects of Voice Development."

To Mr. LEON GASTER, A.M.I.E.E., for his paper on "Progress in Electric Lighting."

To Mr. WALTER GARSTANG, M.A., for his paper on "The Fisheries of the North Sea and the Bearings of Recent Investigations upon the Problems of Supply."

To CAPTAIN G. S. C. SWINTON, for his paper on "London Traffic."

To Mr. BERNARD B. REDWOOD, B.A., for his paper on "Motor Boats."

To Mr. J. B. MILLET, for his paper on "Submarine Signalling."

To PROFESSOR THOMAS OLIVER, M.A., M.D., LL.D., for his paper on "Bridge Building by means of Caissons, including remarks upon Compressed Air Illness."

To Mr. CLAYTON BEADLE, for his paper on "The Development of Watermarking in Hand-made and Machine-made Papers."

In the Indian Section :—

To SIR JAMES A. BOURDILLON, K.C.S.I., for his paper on "The Partition of Bengal."

To DR. GEORGE A. GRIERSON, C.I.E., Ph.D., D.Lit., for his paper on "The Languages of India and the Linguistic Survey."

To COLONEL SIR ARTHUR HENRY MCMAHON, K.C.I.E., C.S.I., late British Commissioner, Seistan Arbitration Commission, for his paper on "Seistan: Past and Present."

In the Colonial Section :—

To THE HON. RODOLPHE LEMIEUX, K.C., M.P., for his paper on "Glimpses of French Canada."

To THE HON. J. G. JENKINS, Agent-General for South Australia, for his paper on "Social Conditions in Australia."

In the Applied Art Section :—

To Mr. LOUIS N. PARKER, for his paper on "Historical Pageants."

To Mr. H. YATES THOMPSON, F.S.A., for his paper on "Some Illuminated Manuscripts of Continental Europe."

To Mr. HARRY POWELL, for his paper on "Cut Glass."

SIR MARCUS SAMUEL, Bart., in proposing a hearty vote of thanks to the Chairman for his excellent address, said the qualifications for the position which Sir Steuart held were very numerous, requiring a knowledge spread over a great variety of subjects, but the Chairman had shown that he possessed them all. He had shown in his address the excellent work the Society was performing in encouraging the expression of opinions on divers subjects, and formulating the very best ideals that could be given in the very large field which lay before the Society.

Sir OWEN ROBERTS, in seconding the motion, said the Chairman had delivered a very excellent sermon. If all sermons were like his, illumined by his humour and his delightful cynicism, he thought the percentage of those who attended church on Sundays (which, he regretted to hear, was only about 18 per cent. of the population) would be greatly increased. He anticipated an exceedingly successful year for the Society under the chairmanship of Sir Steuart, and thought he interpreted the feelings of all present when he said they had spent a delightful evening in listening to a most valuable sermon.

The resolution of thanks was put to the meeting by Sir MARCUS SAMUEL and carried unanimously.

The CHAIRMAN, in reply, thanked the mover and seconder of the resolution for the exceedingly kind words they had used in proposing it, and the audience for the hearty manner in which they had received it. He could only echo Sir Owen Roberts's wish that his year of chairmanship would be a successful one.

THE FRANCO-BRITISH EXHIBITION.

The proposal to hold an exhibition confined to the arts, manufactures, and products of France and the United Kingdom has been received with marked approval on both sides of the Channel. Such an exhibition will be welcome for two reasons. In the first place it will materialise the good feeling which now exists amongst the people of both nations; in the second, it will have the tendency to increase the volume of trade between the two countries. Our commerce with France is already larger than with any other country in the world excepting the United States, and it is capable of considerable increase while it is complementary and not competitive, inasmuch as the products and manufactures of both countries are almost entirely dissimilar.

The suggestion to hold a Franco-British Exhibition was first made in the latter part of 1905 by the French Chamber of Commerce in London, and was brought under the notice of the French Government through M. Cambon, their Ambassador to London. The French Minister of Commerce, M. Doumergue, strongly approved of the proposal, and it was warmly supported by the Comité Français des Expositions à l'Etranger, a co-operative association which acts as the official representative of French industry at all exhibitions outside France in which the Government takes part. The Exhibition was launched at a great meeting held at the Mansion House on July 11, 1906, at which the Lord Mayor presided. The Duke of Argyll, Honorary President of the Exhibition, explained the proceedings of the noblemen and gentlemen who were associated with the project, and resolutions were unanimously agreed to approving the proposal to have a Franco-British Exhibition in 1908, and the proceedings of the committee, authorising the appointment of the necessary committees and the institution of a guarantee fund. It was likewise decided that any profits accruing from the exhibition should be devoted to some public purpose, the exact nature to be determined by the British and French committees.

The organising committee had already entered into arrangements for holding the exhibition on grounds 98 acres in extent at Shepherd's Bush, near the terminus of the Central London Railway, popularly known as the Tube. The locality is admirably adapted for the purpose to which it is proposed to put it, being in immediate proximity to half a dozen railway stations, and in the centre of a perfect network of tramways and omnibuses which connect Shepherd's Bush with all parts of the metropolis and suburbs. The site has been inspected and warmly approved by the French Committee.

In response to a telegram from the Lord Mayor to the President of the French Republic, announcing the success of the Mansion House meeting, a reply was received, through the French Ambassador, to the effect that the French Government would not fail to give its cordial support to the exhibition. Subsequently, at a dinner given in Paris in October by the French Committee to the Lord Mayor, the French Minister of Commerce stated that the French Government had identified itself with the Exhibition.

The project has been received with equal enthusiasm by France and the United Kingdom. At a dinner given by the Fishmongers' Company, in October last, in honour of the exhibition, the Prime Warden expressed his opinion that it would have an excellent effect in further cementing the interests of the two nations, and the British Empire League, at a meeting held on the same day, in the House of Commons, resolved unanimously, on the motion of Viscount Selby, the former Speaker, to give its support to the exhibition, and invited its members to do all in their power to ensure its success. The general committee now numbers more than a thousand persons, including the Duke of Argyll (the honorary president), the Earl of Derby (president), the Lord Mayor of London, a large proportion of the Peers and Members of the House of Commons, nearly all of the Lord Mayors, Lord Provosts, Mayors and Provosts of the great cities and towns of the United Kingdom, the Presidents of their Chambers of Commerce, and he most prominent members of the worlds of finance, commerce, and railways.

The entrance to the exhibition will be adjoining the terminus of the Central London Railway, and the visitor, on entering, will at once find himself surrounded by objects of the greatest interest. The demands for space are already so large that it has been found necessary to supplement the original 98 acres by an adjoining 42 acres, making altogether

140 acres. The grounds will be surrounded by an automobile track, one and a-half miles long, which will be the best and safest in England, and will afford to all persons interested in automobiles, either as owners or manufacturers, an opportunity of testing their cars, and will enable motor races to be run without any danger to life or limb. On the north-eastern portion of the grounds a large area has been set aside for sport. There will be tracks for cycles and athletics, which will surround a considerable space devoted to such games as cricket, football, lacrosse, and lawn tennis. This block of land, in addition to another of greater extent in the north-west intended for amusements and attractions, are contiguous to, but apart from, the grounds devoted to the exhibition proper. The largest building, that devoted to machinery, will contain 321,066 square feet and will be the most considerable one devoted to that purpose in this country. Other important palaces and halls will be the fine arts palace, the new industrial hall, the agricultural hall, the palace of music, the education building, the hall of science, the applied arts hall, and the halls for processes and manufactures. All these structures will be absolutely fire-proof. The material employed in their construction is steel, concrete, and composition stone.

Favourable arrangements have been made with the railways and steamboats, English and French, which connect the British with the French metropolis, and it is confidently expected that passengers from Paris will be able to go direct to the exhibition without change of carriage from the seaport at which they landed, and a committee is being organised to look after the comfort of all visitors from abroad or from the provinces, so that they may be able to visit London and inspect the contents of the exhibition buildings at the minimum of cost, and with the maximum of convenience.

A novel feature will be introduced in the shape of commercial bureaus. A visitor, on entering the exhibition, will be able to discover at once the exact locality of anything which he specially wishes to see, and also to obtain any literature and information about it which may be published. Should he desire to be brought into immediate contact with the artist, manufacturer, or producer, facilities will be given him for carrying out his wishes. There will be branch bureaus in the different buildings so that all persons, whether on business or pleasure, will be able to see what they desire to see with the smallest fatigue.

The restaurants, cafés, and refreshment rooms will be under the management of some of the most famous caterers in France and the United Kingdom, and will be under the control and supervision of the executive committee, who will arrange that the prices inside the exhibition shall not exceed that usually charged in Paris and London for similar articles outside.

The executive have secured the co-operation in the organisation and administration of the exhibition of Mr. Imre Kiralfy, whose experience in such matters is very great.

THE TRADE OF INDIA, 1905-06.

I.

The annual Review of the Trade of India during the year ended 31st March last possesses some interesting features of novelty, for which, doubtless, readers are indebted to its author, Mr. F. Noel-Paton, Director-General of Commercial Intelligence. For instance, the Review opens with a general synopsis of the climatic conditions of the year, which shows very strikingly how dissimilar are the physical conditions prevailing in the various provinces, and how floods, droughts, frosts, and hailstorms operate with an intensity and force unknown in temperate climates. The frontier trade, too, is analysed in much clearer fashion than heretofore.

The grand total of imports and exports of Indian trade declined by 1 per cent., or by 3 crores of rupees (= 2 millions sterling) as compared with the trade of 1904-5. The decline was due to the contraction in the imports of treasure, which in the case of gold receded by 7 crores, principally owing to the strong demand for the metal in Japan and America. Omitting, however, the imports and exports of treasure, the grand total trade (merchandise only) advanced a further 4·2 per cent., imports having risen 6·6 per cent., and exports 2·7 per cent.

Imports of Indian Merchandise.

During the last quarter of a century Indian import trade has more than doubled in value. Among the articles of food and drink, which constitute an important and generally thriving group of this trade, more than half of the total value is represented by sugar. In regard to this produce, the fluctuations in prices have been considerable. The previous year 1903-4 had been marked by the highest price recorded in Bombay of recent years. This was due to several causes. The abolition of the bounties in European producing countries and the consequent reduction of the internal sugar taxes had led to a restriction of cultivation and to an unforeseen expansion of domestic consumption. But as these high prices induced an increase of some 16 per cent. in the acreage sown with beet in Europe, and the utilisation of reserve stocks, a speedy fall in prices soon set in, and prevailed during the greater part of the year 1905-6. As to the countries which send sugar to India, Java, which headed the list last year, has now given place to Austria-Hungary, Mauritius being second. With regard to salt, another product of importance, it is noteworthy that the successive reductions of salt duty have been attended by a growth in consumption. In 1905-6, however, there was a decline of about 4·3 per cent., due in great part to the political boycott of foreign goods. Liquors, which

are divided into three groups, malt liquors, spirits, and wines, showed a substantial progress in 1905-6. In respect of beer, there was a general resort to the lighter and cheaper descriptions, with the consequence that Germany and other foregn countries are slightly gaining on the position of the United Kingdom as a source of supply. The out-turn of Indian breweries appears to be diminishing slightly year by year, but it still keeps ahead in point of quantity with the five million odd gallons imported. As regards spirits, the amounts issued from Indian distilleries are largely in excess of the imports, *i.e.*, about 8¾ million gallons as compared with 1⅝ million. Since February last, the rates of import duty on spirits have been raised, the object being to place imported spirits on a par with native spirits in the matter of taxation. For some years there has been steady decline in the value of wines imported but, in 1905-6, there was a substantial recovery of some 7·1 per cent. in quantity, and 13·6 per cent. in value, the converse in the decline in average value noticed in beer. The imports of foreign tea—which includes tea from Ceylon—remain fairly constant. The quantity rose slightly, with a decline of value, this being due to the fact that the more expensive tea from China is being more and more displaced by cheaper tea from Ceylon.

Coming now to the important group, entitled "Metals and Manufactures of Metals," which includes cutlery, agricultural implements, enamelled ironware, and sewing machines, we note that the aggregate value declined by about 45 per cent., of which the share of the United Kingdom was about one lakh of rupees. Germany, on the other hand, marked an absolute increase of about the same amount, but as the figures for Belgium and Germany are very closely interwoven, the exact share of each is uncertain. The two countries together are progressing steadily. The most notable declines are in Austria-Hungary, a country which used to be supreme in enamelled ware, but whose share has receded from 62 to 40 per cent., while Germany has advanced her's from 31 per cent. to 54 per cent. Metals continued to be imported in greater quantities, 504,160 tons in 1904-5, having risen to 549,863 tons in 1905-6. The total value declined, however, owing to the cheapening of the metals most largely used and the restriction in the imports of some costly metals like copper. The last-named shows an even more marked decline than it did in 1904-5, amounting to 36·5 per cent. in quantity and 32 per cent. in value. The general contraction is a phenomenon of the extraordinarily high level of copper prices throughout the world, the marked activity of the engineering industries having carried prices to an extreme level.

In regard to imports of iron and steel, the year 1905-6 was one of exceptional activity and improved prices. The revival was first felt in America, where business generally has been extraordinarily prosperous, and after midsummer it gradually took effect in the United Kingdom and in India, where the development of the engineering industries and the increase in shipbuilding intensified demand. In regard to iron, the value of the imports was less than in 1904-5, but in the imports of steel there was an increase of 34·7 per cent., this being in accord with the general trend of trade throughout the world. While the United Kingdom improved her position in respect of steel alone, Germany and Belgium registered an advance in both iron and steel. The tin plate trade fell away five per cent. to a value of nearly 37 lakhs of rupees, having been subject to a good many disturbing influences in the past year. On the one hand a great rise in the price of tin itself took place, and on the other hand there was enormously increased production of plates with accumulation of stocks. Imports of lead rose slightly in 1905-6; while tin, like copper with which it is often associated in manufacturing processes, declined to the extent of 46 per cent. in quantity, and 37·5 per cent. in value.

The continuous growth in the importation of machinery is one of the most healthy features of Indian trade, and has been remarkable in 1905-6. The previous year had constituted a record, with imports valued at 402·7 lakhs of rupees, but this total was exceeded last year by 22·2 per cent., bringing the total value up to 491 lakhs. The year has been exceptional, especially in respect of the great activity in the textile industries, jute machinery in Bengal, and, to a less degree, cotton machinery in Bombay, having been largely imported. After textile machinery, rank steam engines and their component parts—electric, mining, and other descriptions.

In imports of railway material there has been fairly continuous expansion during the last four years, the figures for 1905-6 being 673 lakhs of rupees.

Passing by chemicals, drugs, and medicines, which present no special features of importance, we come to tobacco, where the only development observable is in the cheaper sorts of cigarettes, which showed an increase of 23·8 per cent. on the large total quantity recorded in 1904-5, and this in spite of the well-known boycotting movement in favonr of the native-made article. Ten years ago, the imported cigarette was scarcely known to the native community; now the value amounts to 45 lakhs, of which 28 lakhs came from the United Kingdom. The only class of cigarette which declined, was the better quality imported from Egypt.

Mineral oils showed a decrease of 32 per cent., confined chiefly to kerosene; more than half of the decrease was due to the destruction and anarchy in the Baku oil fields.

In the group classed as "Raw Materials," the decline in the imports of foreign coal continues, as the Indian production increases, and the import trade is now governed largely by considerations of freight obtainable on the return journey. The exports in Indian coal, it may be mentioned here, exceeded the figures for the preceding year by over 40 per cent., both in quantity and value, so it is scarcely surprising to see the imports from the United Kingdom and Japan falling off.

Silk is a product liable to great fluctuations, and, in spite of good crops in France, Hungary, and the Levant, the imports into India receded; on the other hand, average prices were higher than in 1904.

The imports of cotton declined from 192,554 to 161,476 cwts., but two years ago the quantity was only 18,279 cwts., so this need not surprise any one. Foreign cottons are used mainly for spinning counts higher than the Indian staple lends itself to, and the strong demand all through India and the East for coarse yarns enables Indian manufacturers to dispense with the imported article at the relatively high prices asked.

Precious stones and pearls, unset, as recorded in the trade accounts, bear no very close relation to the true imports, for it is known that large quantities of pearls are both imported and exported by post so as to escape record. There was a rise of nearly 53 per cent. in 1905-6, nearly half in pearls from Muscat and the Persian Gulf. There was also a large increase of jewels from the United Kingdom. The trade in timber has risen 40 per cent. during the year, following a rise of 37 per cent. in 1904-5, the greater part being due to Siamese teak, which is taking the place of Burma teak.

The very important group of cotton goods was on an unprecedented scale, and reflected the general activity of the world's textile industry, except in Russia. The aggregate value of the imports of cotton yarn and of woven and other cotton goods, was 424 millions of rupees, an increase of 11·6 per cent. In yarns, the increase of value was 37·7 per cent., but the decline in specific value was 7·99 per cent. Yarns from the United Kingdom, which represent 93·5 per cent. of the whole, increased 52 per cent., and since the British exports of yarn in 1905, showed an advance of 25·7 per cent., it may be considered that India took her full share. The imports of dyed and undyed yarns continue to be of nearly equal value.

A comparison of the imported yarn with the production of yarns from Indian mills, shows that in regard to low counts (1 to 25) the imports were quite insignificant, viz., 3 or 4 million lbs. as against 634 million produced in India; of the counts (26 to 40) there was comparative approximation, 33 million as against 45 million lbs., while of the counts above 40, the figures were 5·8 millions, and 1·1 million lbs. respectively.

The imports of cotton fabrics increased in value from 3,555 to 3,901 lakhs of rupees, representing over 37 per cent. of the total imports of private merchandise. The increase is 9·7 per cent., bringing the total increase in two years to 35 per cent. Although, during the last sixteen years, the demand for grey goods has not kept pace with the development in white and coloured goods, the former contributed by far the greater part of the increase in 1905-6. Considering the large contributions now made by the Indian mills to the supply of grey goods, their unprecedented activity in that particular line in the year under review, and the revival in the hand-loom industry (whose output is believed to be double that of the Indian cotton mills), the increase in the imports of these textiles most largely used by the poorer classes must be regarded as a mark of prosperity among the masses. It is noticeable that Bengal, where there are two cotton-weaving mills, took 74 per cent. of the total of imported grey goods in 1905-6. England's shares of the grey goods, bleached goods, and coloured goods are 99, 98, and 95 per cent. respectively. Besides these there are subsidiary goods, such as handkerchiefs and shawls, hosiery, sewing thread, and other manufactures imported. Of the first and third classes the United Kingdom supplies 88 and 85 per cent. respectively. But the considerable item of hosiery is monopolised by Japan, Italy, Germany, Austria, Belgium and Spain.

Silk manufactures, after three years of continuous progress, receded to 190 lakhs of rupees, though the average price improved slightly. In imports of woollen goods there was a reaction of some 21 per cent. in 1905-6, and the total value receded from 307 to 242 lakhs of rupees.

In a long list of "other manufactured goods," including a variety of miscellaneous items, one of the most notable increases is under the head of "Carriages and Carts," which includes motor cars and motor cycles (34,99 lakhs) and cycles (15 lakhs).

Arrangements have now been made, and will soon come into force, by which the true countries of origin will be more correctly ascertained, in the case of goods imported into India. We are nevertheless informed that for some years retrospective comparisons will have to be conducted on the basis of the old system. According to that system, the United Kingdom increased its predominance in imports from 65·2 to 66·7 per cent. The chief other countries rank as follows:—Belgium, Germany, Austria-Hungary, Straits Settlements, and the United States.

Imports of Government stores are not included in these figures. They are large, amounting to 902·7 lakhs in 1905-6, as against 773 lakhs in the previous year, and the share of the United Kingdom, though it is marked by an absolute increase in value, declined from 94 to 90 per cent. of the total. Material for State railways, forms a considerable part of this heading.

INSANITY.

The sixtieth Report of the Lunacy Commissioners shows that the total number of notified insane in England and Wales continues to increase. On the 1st of January, 1906, it stood to the estimated population in the proportion of 1 to 283, or 35·31 per 10,000 of the population, an increase of 0·62 per cent. on the ratio for last year, contrasting with an actual numerical growth of 1·79 per cent. In 1897 the ratio was 31·89, so that in the decade it increased 10·72 per cent., the proportion of insane

persons in the community rising from 1 to 314 to 1 to 283. The actual increase in the population during this period has been 10·8 per cent., and in the total number of insane under care 22·7 per cent. This does not necessarily imply, as the Report points out, a corresponding increase in insanity, but only of persons detained under care. The population of England and Wales has increased from 22,223,299 in 1869, to 34,547,016, *i.e.*, 55·4 per cent. in 1906; the total insane on the 1st January, 1869, was 53,177, on the same date in 1906 it had increased to 121,679. The admissions during the year 1869 were 10,472, during 1905 they were 21,622, an increase of 106·4 per cent., but the ratios have not increased to a like extent, being less than the increase in population. If the relative distribution of the pauper insane at the present time is contrasted with that obtaining in 1859, the first year for which there are accurate statistics for the comparison, the contrast strikingly shows to how large an extent this class is now cared for in special institutions. In making this comparison, the asylums of the Metropolitan Asylums Board, which date from 1870, are ranked. On this basis it will be found that, whereas in 1859 the proportion detained in asylums, hospitals, and licensed houses was 56·2 per cent., in 1906 it is 84·9 per cent. On the other hand, whilst in 1859 the proportion in workhouses was 25·4, it is now 10·0 per cent., or, if the metropolitan district asylums be classed with workhouses, 16 per cent.

The increase in the numbers of the insane has taken place year by year although not with equal proportions. Taking the last decade, it will be found that as between the figures for 1896 and 1906 respectively there has been a total increase of 26·5 per cent., whereas the annual increase has ranged from 1·03 in 1900-1 to 2·08 in 1903-4, receding to 1·08 in 1905 6. It is interesting to observe that the numbers annually admitted into institutions and in single care do not follow the general rates of increase, for whilst in the whole decade they increased 16·8 per cent., they had, up to 1902, increased as much as 23·4 per cent., there being during the following years an actual diminution in the proportion amounting in all to 6·6 per cent. A similar result follows a study of the figures for first admissions since 1898, for though up to 1902 the increase on the 1898 figures amounted to 22·4 per cent. (of which as much as 10·1 was in 1901-2) the total increase by 1905 had fallen to 14·7 owing to the falling off of such admissions in the past three years.

The Report touches upon the question how far the cause of an attack of insanity is related to the occupation of the patient. It is a subject worthy of careful and detailed research but the data available only permit of an approach to the fringe of it. As a contribution the Commissioners have singled out for special analysis the returns from four asylums receiving patients from communities whose pursuits are mainly agricultural, namely, Cambridge, Dorset, Wilts, and Hereford. The period dealt with is the three years 1900-2 inclusive, during which there were admitted into these asylums on an average annually 220 males and 256 females. The original causes of insanity in these cases were then compared with the average in all asylums for the five years 1899-1903 inclusive. The general result was to show that in these counties the causes which were above the mean were religious excitement, sexual decay, sunstroke, privation, old age, hereditary influence, and congenital defect, whilst those below the mean were domestic trouble, adverse circumstances, mental anxiety, fright and shock, intemperance in drink, and a few others. The statistical result bears out what may have been assumed, *à priori*, in the case of rural communities, where the lack of brain activity may conduce to the dementia that accompanies old age, intermarriage favours transmission of feeble brains and congenital deficiencies, avocations expose to risk of sunstroke, low wage earning may be responsible for privation, and revivalism in religion may be more potent in disturbing mental balance than grief or anxiety. The returns on the type of insanity exhibited by the patients admitted into institutions other than idiot establishments show that during the five years 1900-1904 inclusive, there were annually in every 100 admissions 5·4 who were subjects of congenital insanity, 40·7 cases of mania (all forms), 30·5 of melancholia (all forms), 40·1 of delusional insanity, 6·6 of general paralysis, and 12·7 of dementia (all forms). The Commissioners say they have frequently had occasion to complain that persons of distinctly unsound mind were detained, or allowed to remain, in workhouses without the requisite legal authority; and of the inadequacy of the means of escape for imbeciles in many of the houses in the event of an outbreak of fire. The Commissioners are able generally to report favourably on the ordinary workhouses visited by them during the year.

BUCHAREST EXHIBITION AND ROUMANIAN ASSOCIATION.

In commemoration of the forty years' reign of Charles I., an Exhibition is now being held at Bucharest, where the fifth Congress of the Roumanian Association of Science has also assembled during the month of October. The number of members who joined the congress amounted to 4,000, almost double the number who attended the last meeting of the British Association. Judging from the importance of the papers read and the discussions following, there is noticeable a distinct advance in the appreciation of the value of education on the part of the Roumanians.

The Congress was divided into ten sections, the best attended being the one dealing with Educational Science, comprising over 3,000 members, including university professors, and teachers of all classes. Great attention was given in this section to the

question of extending the number of hours at schools prescribed for physical training and military drill.

The Economic Science Section was also well attended, and great interest was attached to the papers read dealing with the improvement of the state of the peasantry, a subject which engages the attention of all political parties of the country. The outcome of this meeting has been the inauguration of a special society, starting with over 200 members, and having as its object the thorough investigation and discussion of the social and economical problems of Roumania.

One of the characteristic features of the Congress was the fact that, for the first time the clergy as a body, participated by forming a separate section, and among other questions discussed, the scientific aspects of religious teaching received considerable attention.

Among the other sections in which good work was done, mention may be made of the Medical, Physical, and Chemical Sections. On the whole, over 160 papers were read. The next Congress will take place September, 1907, at Focsani.

GERMAN COAL SUPPLY IN 1906.

According to a recent report by the American Consul at Munich, the coal supply from German mines, for the large industrial cities of Germany, in the first half of 1906, was not equal to the demand. The supply increased 8 per cent. from 1905 to 1906, and 12 per cent. from 1904 to 1905, although in the last-named year the trade was retarded for two months by a strike. The causes given for the short supply this year are lack of labour in mining and an insufficiency of cars for transporting the coal. This lessened increase in the supply is certainly not caused by a lessened demand, as all branches of industry have shown great progress in the first half of the current year. The twenty largest industrial cities in Germany used 8,100,827 tons of hard coal in the first half of 1906, 7,429,778 tons in the same period of 1905, and 6,618,984 tons in the first six months of 1904, showing an increase of 671,049 tons, or 8 per cent. in the current year, and of 810,794 tons, or 12 per cent., last year. The supply in the first quarter of the present year was even smaller in quantity than in the same period of last year, which may, however, be explained by the fact that most consumers and speculators laid in large stocks last year to provide against the threatened strike. The supply to the largest industrial cities in Germany for the first six months of the present year was as follows:—Berlin, 2,541,704 tons; Leipzic, 900,190; Cologne, 770,763; Dresden, 530,668; Frankfort, 424,774; Magdeburg, 345,404; Munich, 340,606; Altona, 276,746; Barmen, 266,391; Nuremburg, 202,135; and Halle, 177,068 tons.

ARTS AND CRAFTS.

Writing and Illumination.—When once the printing press was firmly established the art of beautiful writing began to die out. It is true that in the sixteenth century some beautiful writing books were produced, but after that, although books about writing did from time to time appear, they were by people who looked upon the art from the point of view of the writing master, not of the scribe. They taught the would-be learner how to cultivate perhaps a delicate Italian hand, or to make flourishes worthy to adorn an address, or to ornament the beginning of a legal document; but their authors would have been astonished—not to say shocked—at the suggestion that this writing of theirs should be used in the same way as that of the professional scribes who spent their lives in writing in the days when printing was not. When, in comparatively recent years, the typewriter (with its usually quite unnecessarily ugly type) had gained a firm footing on the market, it seemed that the last hope of getting people to write even good, legible, every-day hands was gone. The illuminated addresses, too, of a period within the memory of most of us were so ostentatiously ugly that they seemed past praying for. And yet, even when things were apparently at their worst, something was being done. Opposing schools are very much inclined to overestimate, or to underestimate, as the case may be, the artistic work of William Morris, but there can be little doubt that he was interested in writing long before the art was receiving any public attention, and that the exhibition, a few years ago, of some of the books which this most impatient of men had so patiently written and illuminated was really the starting point of the popularity which writing now enjoys with a certain section of the community. And, though Morris's writing is not the model of that which is being so largely taught and so diligently practiced at the present day, this is not by any means unallied to it.

Script.—The writing which is so much in vogue to-day is of rather too laborious a kind for the purposes of every-day life. Indeed, it is rather surprising that in this bustling, hurrying, commercial twentieth century it should ever have come into fashion at all; but it has done so, and with a truly amazing rapidity. Ten years ago it wonld not have occurred to anyone to show a page of manuscript at any exhibition; to-day pages or books of "script," as it is usually called, form a feature of every show which takes to itself the name of Arts and Crafts. Some of the work is in Roman capitals, but the form of letter usually adopted is the uncial or half uncial. Apparently all the writers have founded themselves on these models, and very few of them have the individual character which would make it easy to distinguish readily the work of one writer from that of another. This explains itself when we realise that, though the subject is taught in many schools to-day,

the teachers are practically all of one school—trained at the Central School of Arts and Crafts, where the study was apparently introduced, not more than seven years ago. Within these last few years not only has the art attracted a good deal of attention, but it has really become quite the rage, and it creates no more surprise now to learn that an amateur is taking lessons in script than it would have done some years back to be told that he (or she) had taken to poker work. One feels, indeed, that the ample space devoted to writing in Mr. Edward Johnston's recent book is no more than the exigencies of the moment demand, and it is satisfactory that his most practical and useful information has appeared at a time when so many people are likely to profit by it. So far as the fashion has produced a class of scribes who can on occasion write legibly and prettily, and with a due appreciation of the proportions of the page, it has really done good service. Moreover, the re-introduction of a good standard of writing has made those responsible for addresses, testimonials, &c., take more care to get a fairly well executed piece of work —or perhaps it would be more accurate to say that since they have not had so far to go in search of good work, they manage to get a better type of writing than that which would have contented them say twenty years ago. Still one rather wonders why the art is so popular. Fine writing is, without doubt a most fascinating accomplishment—but there is a uniformity, even a want of individuality about much of the modern script strangely at variance with the acute desire for self-expression at all costs, which is so characteristic of the modern artist-craftsman. Again, though script is neither so slow nor so laborious as it looks, it is slow compared with ordinary writing, so that few people adopt it for ordinary purposes, and at the same time it does not by any means always influence the ordinary handwriting of those who practice it. This being the case, it is natural to enquire what will become of all the scribes? There is, after all, a very limited demand for testimonials and addresses, and the market for written books in these days of cheaper and ever cheaper printing, is bound to be a small one, and confined to the few who have long purses. Everyone must be glad that writing as an art has made the advances which it has done in these last few years. If there is any cause for regret, it is only that it has gone so entirely in one direction, and that one which, though admirable in itself, does not touch very closely the everyday life of the twentieth century.

Illumination.—From one point of view it is difficult to say where writing ends and illumination begins—but though in the recent revival the two arts have naturally gone hand in hand, the scribe and the illuminator are not necessarily one and the same person; and whilst the modern writers have founded themselves almost exclusively on one model, the illuminators of the present day have taken their inspiration from widely different places and have occasionally also struck out new lines for themselves. The more modest of them have contented themselves with renderings of Celtic ornament and interlacing, or with flowing scrollwork of the Gothic type, and have left figure work severely alone. There are artists, however, who aim at something a good deal more original than this, and amongst them Miss Kingsford, at least, has produced most elaborate and minute figure decoration, so delicate in colouring and so refined in treatment that it challenges comparison with the best of old work, whilst two or three other illuminators are doing work which, though far from simple, is very satisfactory. Illumination, naturally, is generally associated with writing but there is at least one worker (Mr. Vigers) who has tried with some measure of success the promising experiment of adding his hand illumination to printed books. Of course, the books thus adorned are, specially and very carefully printed, and the ornament is added to the pages before they are bound.

Lettering.—It is rather curious that the revival of writing has had so little effect upon lettering in general. Now and again we see the tickets in a shop window, or some other small announcement or advertisement, neatly set out in uncials or half-uncials instead of being adorned with the flourishes of the signwriter—but this is the exception rather than the rule. This is probably due partly to the fact that a quite considerable interest had been aroused in lettering in general some time before script became a subject of interest, and still more to the great variety of lettering demanded by different positions and different uses. Forms essentially suitable to writing would not, naturally enough, be equally satisfactory cut in wood or carved in stone. Still, the fact remains that while during the last few years the lettering on posters, advertisements, showcards, calendars and the like has been getting steadily better, its progress has been upon lines which have had little or no connection with script. Many eccentric and illegible alphabets have seen the light, letters have sometimes been distorted till they were all but unrecognisable; we have had a large variety of high-crossed A's, of H's sloping upward to a point, and of microscopic O's (these last, as some of the perpetrators were naive enough to admit, because big O's were so difficult to draw), and other absurdities. And it cannot be denied that commonplace, eccentric, and ugly lettering still abounds. One has only to look at the advertisements to see that there is plenty of room for improvement. For all that, lettering seems to be receiving much more serious consideration than it did. The average person has begun to be aware that lettering counts for something, and that it is possible to make or mar a design by it. And every now and again we do see posters and other advertisements, well lettered and carefully spaced, which show a desire to attract attention by their taste rather than by their vulgarity.

GENERAL NOTES.

BARCELONA INTERNATIONAL ART EXHIBITION. —The Board of Education have been informed through the Foreign Office that the municipality of Barcelona propose to hold a fifth International Art Exhibition in that city from the 23rd April to the 15th July, 1907, which may again be opened in September and October. The Exhibition will comprise the fine arts and art crafts generally. The time for receiving exhibits will extend from the 15th to the 30th March. Copies of the regulations containing particulars of the conditions upon which exhibits will be received and awards made may be obtained from the Spanish Consul-General in London, Senor Joaquin M. Torroja, 40, Trinity-square, E.C.

MANNHEIM HORTICULTURAL EXHIBITION, 1907. —The Board of Agriculture and Fisheries are informed that a Horticultural Exhibition will be held at Mannheim in the Grand Duchy of Baden from May to October, 1907. Exhibits from this country will be admitted to the fruit, vegetable, orchid, and cactus shows. Applications for information should be addressed to the Office of the Exhibition, Friedrichsplatz, 14, Mannheim, Germany. A copy of the provisional programme can be seen at the Offices of the Board, 4, Whitehall-place, S.W.

TRADE WITH PERSIA.—Some of the difficulties which handicap the trader who wishes to do business with Persia are indicated by His Majesty's Acting Consul-General in Khorassan, Major Kennion, in his report (Cd. 2682) just issued. Law, as understood in the United Kingdom, is practically non-existent in Persia. All questions which cannot be settled by arbitration are settled in the Karguzar's Court, nominally according to the Shariat, or religious law. On claims recovered in this manner fees are charged by the Karguzar amounting to 5 per cent. of the net amount. As to trade usages, Persian merchants are in the habit of acknowledging them or denying them as their own interest may seem to indicate for the time being. The foreign trading community especially feel the lack of laws dealing with—(1) Fraudulent bankruptcy; (2) identification of debtors' seals and signatures; (3) the payment of acceptances; (4) the enforcement of contracts; (5) noting and protesting bills of exchange. It follows that great care has to be exercised in ascertaining the character of Persian merchants before dealing with them if loss is to be avoided. Major Kennion says the Manager of the Imperial Bank of Persia at Meshed would usually be able to give useful advice in such matters. Notwithstanding the war and internal dissensions, the Russian monopoly of the supply of everything which she can produce seems to be still practically unchallenged. Other things being equal, it is impossible for British and Indian goods to compete with those of Russian origin in Khorassan. Favourable geographical conditions are the main factor in favour of Russia, whose organisation and methods are also superior. Russian merchants, recognising that those of Persia have little money and less enterprise, have invented a system by which, on making a small deposit, a trader can order goods and defer payment until he has actually sold them, or at any rate has purchasers in view.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 26...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. D. Hall, "Artificial Fertilisers: their Nature and Functions." (Lecture II.)

East India Association, Caxton-hall, Westminster, S.W., 4 p m. Mr. L. W. Ritch, "The Burden of the British Indian in South Africa."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. H. Blake, "Some Notes on Sanitary Law."

University of London, South Kensington, S.W., 8 p.m. Mr. Banister Fletcher, "The Parthenon." (Lecture III.).

Actuaries, Staples-inn-hall, Holborn, 5 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. R. Blathwayt, "Egypt: Past and Present."

TUESDAY, Nov. 27...Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. W. A. P. Tait, "The Talla Water Supply of the Edinburgh and District Waterworks." 2. Mr. M. Ratcliffe Barnett, "Repairing a Limestone-Concrete Aqueduct." 3. Mr. E. P. Hill, "The Yield of Catchment-Areas."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. T. Manly, "Ozobrome."

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. J. C. Mellis, "St. Helena."

WEDNESDAY, Nov. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. John William Gordon, "Patent-law Reform."

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, Nov. 29...Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Rev. W. Manning, "The Middle Class."

FRIDAY, Nov. 30...Civil Engineers, 25, Great George-street, 8 p.m. (Students' Meeting.) Mr. P. A. Spalding, "Applications of Electricity in Printing Works."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m, Annual General Meeting.

Royal, Burlington-house, W., 4 p.m. Annual Meeting.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Discussion on Mr. Clarkson's paper, "Steam as a Motive Power for Public Service Vehicles."

Journal of the Society of Arts.

No. 2,819. VOL. LV.

FRIDAY, NOVEMBER 30, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 3, 8 p.m. (Cantor Lecture.) A. D. HALL, M.A., "Artificial Fertilisers: their Nature and Functions." (Lecture III.)

TUESDAY, DECEMBER 4, 4.30 p.m. (Colonial Section.) Sir LEWIS LLOYD MICHELL, "The Cape to Cairo Railway."

WEDNESDAY, DECEMBER 5, 8 p.m. Ordinary Meeting.) Colonel SIR CHARLES M. WATSON, K.C.M.G., C.B., "The Metric System."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 26th inst., Mr. A. D. HALL, Director of the Lawes Agricultural Trust, delivered the second lecture of his course on "Artificial Fertilisers: their Nature and Functions." The lectures will be published in the *Journal* during the Christmas recess.

NORTH LONDON EXHIBITION TRUST.

In 1865, the Committee of the North London Working-classes and Industrial Exhibition (1864), presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the award annually of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. These have been awarded, for the present year, as follows:—

1st prize (£7 7s.) to F. C. LATTER, for a Modelled Design for Fountain.

2nd prize (£4 4s.) to A. G. SPENCER, for an Engraved Copper Plate.

3rd prize (£3 3s.) to F. E. MEKELBURG, for an Engraved and Enamelled Cross, and Designs for Engraving.

ADJOURNED MEETING.

The discussion on Mr. John William Gordon's paper, read on Wednesday evening, 28th inst., was adjourned until Wednesday, January 16th, 1907.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 28th, 1906: Sir WILLIAM H. PREECE, K.C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Blake-Thomas, Hugh, Cawsand, Pwllheli, North Wales.

Bradley, Benjamin Lawrenson, Barn-ith Wood House, Grindleford, Derbyshire.

Middleton, Robert Hugh, 26, Selborne-road, Ilford, Essex.

Muntri, Kashinath Gorindjee, 192, Worlee, Bombay, India.

Shaw, Mrs. W. T., Hypatia-lodge, Percy-villas, Campden-hill, W.

Smith, Harry E., Wrexham-house, Winn-road, Lee, S.E.

Stewart, James Ernest, care of The Pekin Syndicate, Limited, Tientsin, China.

Wilberforce, Professor Lionel Robert, 5, Ashfield-road, Aigburth, Liverpool.

Wild, Albert Edward, care of Messrs. Henry S. King and Co., 65, Cornhill, E.C.

The paper read was—

PATENT-LAW REFORM.

By John William Gordon.

The reform of the Patent-law, a subject which is always more or less occupying public attention, is a matter with which the Society of Arts has in times past had a very special connection, and the discussion of the subject within its walls at the present time has therefore a peculiar fitness. For it was announced in the daily newspapers about the middle of last month that the Government would shortly bring in a Bill to amend the law relating to industrial patents, and it certainly is suitable that when a measure of that sort is in course of incubation its scope and provisions should be taken into consideration by this Society.

It is the more desirable that a body such as this Institution, which has a very honourable record in connection with the greatest reform of our Patent-laws ever attempted at one stroke, should now be heard, because in the discussion of the proposed reforms both critics of the existing law and propounders of new clauses are apt to forget that the patent law of the United Kingdom is a very venerable fabric, in which the British public may fairly be expected to take a reasonable and inoffensive pride.

A Patent-law is now an integral part of the legislation of almost all the civilised countries of the world, in fact, its establishment may perhaps be said to mark the stage at which industry escapes from the thraldom of patronage and the shackles of monopolies to become a freely developing and spontaneous growth, a self-contained and self-supporting department of the national activity. The Patent-laws of the world, numerous and various as they are, are all, directly or indirectly, derived from the Patent-law of this country. With us the Patent-law is indigenous. It has been formed to shape and use by strokes of fate which from the beginning of the sixteenth century have resounded through our national history. Little by little it has acquired consistency and system until at last it has arrived at such completeness that it can be embodied in a code and transferred as a whole, with such modifications as the wisdom or fancy of the borrower suggests, to the statute-books of other States. To the United States and to some of our own colonies the germ of our Patent-law was conveyed with the common law, which they inherited from the Motherland, but in countries like the various States of Europe, which have received from our system of law nothing but what they have expressly selected for appropriation, the scheme of our patent system has furnished a model upon which they have worked in the construction of their own systems and a model from the main lines of which no one of them has thought it wise to depart.

There is therefore much reason for a reverential feeling with respect to the British Patent-law, and it hardly can be matter of reproach that those who undertake its reform should wish to make themselves acquainted with its history. I assume, therefore, that in bringing this subject under your consideration this evening I may count upon your patience if I introduce what I have to say with a cursory sketch of the history of reform in our own Patent-law.

In speaking of the reform of Patent-law I refer, of course, to the law concerning patents for new inventions. It is no doubt true that Patent-law, in the full sense of the term, is concerned with all kinds of grants which pass the Great Seal. And it is equally true that for a full comprehension of the Patent-law it is necessary to have regard to those many matters, other than new inventions, which from time to time are treated in this way. But patents for inventions form a class apart, so completely separated from patents of other kinds that in common usage a patent and an invention not seldom mean the same thing, and for present purposes no object would be served by including patents of peerage, of precedence, and of a thousand other matters, in the survey.

The earliest reform in the law relating to patents of the kind which now concerns us was introduced by King James I., and, in fact, had very far-reaching consequences. Under his immediate predecessor on the English throne the mischief of monopolies conferred by patents had assumed very formidable dimensions, and had given rise to still more formidable discontents. While Queen Elizabeth lay on her death bed, the common law concerning grants of trading privileges was formulated in the famous case of D'Arcy against Allin, a decision reported by Sir Edward Coke under the title of "The Case of Monopolies." That decision—although rendered in a test case which had been specially remitted by the Queen to the Court of Queen's Bench for the determination, not only of the issues of fact, but also of the principle of law—was very unacceptable to the Court, and for a long time King James held himself in reserve upon the point, studying it, no doubt, as he studied other

points in the law, to him unfamiliar, of his southern kingdom. In 1610, however, when he had occupied the throne for seven years, and, as he himself said, had served a full apprenticeship to the craft of a king, he took and proclaimed a decision which was destined to become in later times the corner stone of the law of industrial privilege all the world over, and he devised a procedure which, for upwards of two hundred years, continued without change to be the machinery by which patent grants were applied for and conferred within this realm. The proclamation was issued in book form by the King's printer, and bears the quaint title—"A Declaration of His Majesties Royall pleasure, in what sort He thinketh fit to enlarge or reserve Himself in matters of Bountie." Sir Edward Coke, in his "Institutes," speaks of it more compendiously as the King's Book, and it is cited in the Statute of Monopolies as a publication in print containing "Your Majesties Declaration."

That part of King James's book which deals with machinery is now of purely antiquarian interest, and, although its antiquarian interest is very great, it must not detain us this evening. The pregnant sentence which has developed into a practically universal Patent-law at the present day is contained in the following words:—

"A memorial of those suits wherein we are contented to be moved by our servants and subjects, and to reward them according to the particular merit of the suitor. . ."

"9. Projects of new invention so they be not contrary to law nor mischievous to the State, by raising prices of commodities at home, or hurt of trade, or otherwise inconvenient."

King James's reform, had he succeeded in making it effective, would have completely satisfied the reformers of his own time, but it was much easier to formulate a rule of that sort than to enforce its observance, and consequently his effort did more to fix and define the popular demand for reform than to satisfy it. People said with irresistible force that inasmuch as grants had notoriously continued to be solicited and made in defiance of the proclamation, what was wanted was, not a mere re-issue of the Declaration, of which a second edition appeared in 1619, but a statute which should actually invalidate and set aside all these unwarrantable gifts, making them, not only irregular, but actually illegal.

With this object the Statute of Monopolies was passed in 1623, not without difficulty, as we know, nor without considerable opposition in behalf of the Crown and on the part of its wearer, as we infer from what Sir Edward Coke says about the matter. Nevertheless the Bill was passed embodying the sense and enacting the words of the King's own declaration. Very elaborate subsidiary clauses, intended to preclude all possible evasion, made up the bulk of the statute, but its kernel is contained in the sixth section, which exempts from the general denunciation of all restraints upon trade such patents for new manufactures as are granted

"For the term of fourteen years or under . . . of the sole working or making of any manner of new manufactures within this realm to the true and first inventors of such manufactures which others at the time of making such letters patents and grants shall not use, so as also they be not contrary to law nor mischievous to the State by raising prices of commodities at home or hurt of trade or generally inconvenient."

While the Legislature and the Courts were thus busy with the determination of the rule of law the Law Officer of the Crown was occupied with a less conspicuous reform and one which has had less permanent and less widespread consequences, but is of very particular interest to reformers of the Patent-law at the present day. The most exasperating of all the wrongs inflicted by patentees upon the community was an injunction. Injunctions in those days were not issued by Courts of Common Law, but were the common form in which relief was afforded by the Privy Council sitting for judicial purposes either in the Star Chamber or at the Council Board. The Privy Council exercised an extraordinary and discretionary jurisdiction which has been aptly described as criminal equity. Riots, contempt of the King, or of his officers, the maintenance of wrongdoers, or any offence against public order and government, which, by reason of the rank of the offender or of the force engaged upon the side of rebellion, threatened the peace, and was capable of offering an effectual resistance to the authority of the ordinary courts of law, came within the cognisance of the Privy Council, and the Privy Council disposed of forces much greater than the rudimentary police which enforced obedience to the Courts of Common Law. In turbulent times and for really public purposes a court like the Court of Star Chamber was invaluable, perhaps indispensable. At its worst it was notably better than those forms of anarchy which find favour in modern States,

and which, when irregular in origin, are called lynch law, and are named martial law when regularised by a legislative Act.

The general term by which all offences cognisable by the Privy Council could be denoted was contempt; sedition was contempt of the King's authority; maintenance, contempt of court, and so forth, just as in the Old World formula of an indictment at the present time, a crime charged against a prisoner is said to have been committed "against the Crown and dignity of our Lord the King." This is simple enough, and if the Star Chamber had confined itself to such great contempts as threaten the very existence of social order, it might not improbably have continued to this day an integral and indispensable part of the British constitution. But the doctrine of contempt was seized upon by the Court and the courtier party as an engine for extending the authority of the Crown at the expense of the popular franchises. If the Privy Council could restrain gross contempts, *à fortiori* it could restrain petty ones. So patentees sought its forum—they produced their grants, complained that infringers were treating the Royal Ordinance and the Great Seal with high contempt, and asked for injunctions to restrain infringements on that ground. In an evil hour for its reputation the Privy Council acceded to this demand. It entertained their suits and established a summary process for enforcing obedience to the King' grants. If a patent had been wrongly granted there was a Lord Chancellor with jurisdiction to cancel it, and there were courts of law which could investigate the question of validity. To them the oppressed public might have recourse to be relieved from an oppressive grant, but while the Seal remained upon the parchment it was high contempt to refuse obedience, and such contempt must be restrained by admonition and injunction, and punished by imprisonment and fine. Such seems to have been the doctrine of the Star Chamber and of the Council Board.

In the Statute of Monopolies this mischief is redressed by a clause which removed all questions arising upon patent grants from the jurisdiction of the Privy Council, and gave, in reference to these matters, an exclusive jurisdiction to the Courts of Common Law. About the same time—but this date cannot now be precisely ascertained—some law officer attacked the same problem from the other side. Who he was we do not know, but it is interesting to reflect that he may well have been Francis Bacon or Edward Coke. Both these great lawyers were much occupied with the reform of Patent-law, and each of them, we may be sure, would have approved a plan which mitigated the irrational harshness of Privy Council law. Whoever he was, he incorporated in the grant itself a proviso to the following effect:—

"If at any time hereafter it shall appear to us, our heirs and successors that this our grant shall be anyways prejudicial to our commonwealth or otherwise . . and after that declaration thereof shall be made by us under our privy seal . . . . or by any six or more of the Privy Council of us, these our letters patent and everything therein contained shall from thence-forth cease and be utterly void and frustrate."

The reference here to "six of our Privy Council," points unmistakably to the judicial Privy Council, for of that committee, six formed a quorum from the days of Edward VI. to the time of its abolition in 1640. The idea then, seems to have been this. That a defendant when convented before the Board would no longer be defenceless, though entitled to a good defence. He would answer the charge by denying the contempt, and support his denial by citing the proviso in his favour. Thus, even if the courtiers and patentees should succeed in getting the Statute of Monopolies repealed, or its provisions set at naught, they would find themselves confronted on the ground of their own choosing, with a royal defence of the popular liberties. So by the co-operation of all parties in the realm, by the deliverance of the judges, corroborated by the king's proclamation, ratified by Act of Parliament and completed by the ingenuity of the Law Officer of the Crown, the first great reform was brought about, and the broad foundations of an industrial Patent-law were securely laid.

It was long before any further reform was undertaken, and when it was eventually called for the demand arose chiefly out of the considerable part which James I. assigned in his system of procedure to the king himself. Twice was every application to be brought under his personal notice, and twice were the papers to receive the royal sign manual before a grant could be made. With the increased number and urgency of such applications in the times of George III. and of George IV., and with the delays which those monarchs introduced into the conduct of the business of a king, the Stuart system broke down hopelessly. Moreover, fees would seen somehow to have increased during the interval, and between expense and delay the granting of in-

dustrial patents was, in 1829, a branch of the public service which had fallen into scandalous disarray. In that year, a Parliamentary Committee sat to inquire into the subject, and subsequently made a report, which is a mine of information and suggestion, relating not only to the Patent-law of this country but to the principles and philosophy of Patent-law in general. The recommendations of that Committee did not, however, bear immediate fruit. Matters of more poignant interest absorbed the attention of Parliament and of the nation. The Reform Act of 1832 and the Corn-law agitation obscured those lesser matters—momentous as they were—which were bound up with Patent-law reform, and prior to 1852 only a few fragmentary and comparatively small changes were effected and those, such as they were, owed their form and promotion to that indefatigable law reformer, Lord Brougham. In the years immediately preceding 1850, however, a new influence made itself felt. The Society of Arts, founded in the middle of the eighteenth century, received about this time a great accession of strength. The time itself was propitious to reform. Law reform on a large scale had been carried through by Romilly and Brougham. The reform of representation had given new life to Parliament. The reform of taxation had made a good beginning with the repeal of the Corn-laws, and the thoughts of men were being visibly "broadened with the progress of the suns." The time seemed propitious also for carrying to completion the work of stimulating and directing industrial enterprise in this country, which since its foundation in 1754 had been the principal object of the Society of Arts. From very small beginnings it had developed a system of industrial exhibitions at which producers and manufacturers competed with one another for pre-eminence and carried on a commerce of ideas. At first such exhibitions were necessarily local institutions. Gradually, as they grew in popularity, they extended the range of what may perhaps be called their jurisdiction, and drew upon the whole kingdom for contributions and support. In this way the Society's exhibitions acquired a national character and a success which led to the adoption of the idea in other countries. Thus the notion of industrial exhibitions and acquaintance with the ends which they could be made to serve grew to be widely diffused. The national naturally suggested the international exhibition, but when that proposal took shape it met at first with strong opposition and denunciation. For the manufacturers of a country to exchange ideas with one another and to compete among themselves was reasonable enough and experience had shown it to be highly useful, but to invite foreigners to their councils would be madness, to lay themselves out to entertain foreign competitors would be Quixotic, to open a great fair at which foreign producers and manufacturers would be given free access to the home market, suicidal. The opposition can easily be understood. By what means it was met and overcome I do not know. I suppose that the fact is that in the career of every great people there are accesses of power, times of conscious strength and clear vision, when it can rise to the height of a great argument untroubled by timid fears or shallow prejudices and that the middle of the last century was such a moment in our history. Howsoever it come about, the fact is that the task which the Society undertook was successfully accomplished, the nation was persuaded to make the bold stroke, and the International Exhibition of 1851 inaugurated a new phase of the comity of nations, a phase which gave an innocent and co-operative aspect to international industrial rivalries.

The general results of the first International Exhibition do not this evening concern us, but its effect in promoting the reform of Patent-law was so marked as to furnish a second chapter to the story which I have to tell. The Exhibition of 1851 brought not only foreign visitors but also our own colonists to our shores in great numbers, and advantage was taken of their presence to elaborate a system of Patent-law applicable, not to the United Kingdom only, but to the British empire as a whole. Colonial patents down to that time had been few and, for the most part, issued, not under local statutes, but under the prerogative of the Crown. The men of that day saw a future for the British empire to which such primitive arrangements were wholly unsuited and, considering its requirements as a whole, they elaborated a scheme for bringing into existence what may be called an imperial patent grant. In outline the scheme was this. The holder of any existing British patent might apply in a colony in which his patented manufacture had not been introduced for local registration of his British grant. The effect of registration, when obtained, was to cause the original patent to run in the registering colony, and thus for the remainder of his term the patentee in Great Britain acquired the rights of a local patentee. In some colonies the

registration scheme was adopted, side by side with and as supplementary to a system of local patents. In other colonies it became what to this day it is in the colonies of St. Helena and the Falkland Islands, the only form in which a local patent grant could be obtained. But whether in substitution for or in supplement of a local grant, the system of local registration seems to have been a scheme most admirably adapted to the circumstances of a complex organism like the British Empire. The inventor who secured a British patent became immediately free of a great family of States. He could perfect his invention, complete his experimental work, accumulate capital, and when in this way his manufacture was a going concern, he could start a branch establishment in such colonies as required his industry under the protection of what was substantially a local patent for the residue of his original term. Such a system was the worthy product of a great age, and may reasonably have inspired the hope that in time to come the slow working of this common Patent-law would create a widely ramifying industrial system which would powerfully promote commerce between the various members of the whole, and create bonds strong though impalpable which would hold the daughter States to the Mother Country, ever growing in strength, but never liable to bear with hard or hurtful pressure upon any part.

But to the realisation of that fascinating hope something more was necessary than a scheme of Colonial laws. If the British grant was thus to become the source from which so large a stream should flow, it was important that the machinery for granting patents in Great Britain should be put in thorough working order, and this was accordingly taken in hand and carried out by the passing of the Patent-law Reform Act of 1852. The cumbrous machinery devised by King James for preventing the abuse of the Royal prerogative was replaced by simplified forms of application and more summary methods of dealing with the application when made; and a small Board of Commissioners, with an office and official staff, was substituted for the Home-office, Privy Seal, Lord Chancellor, and other departments through which, under King James's scheme, the luckless inventor had to run the gauntlet of official criticism. Minor improvements accompanied this great reform. A large reduction of fees made patents more available than before, and the introduction of the provisional specification closed the main door previously open to fraud. Prior to 1852, as now, the patent was granted for an invention specified only by a title in the grant itself. The nature of the invention denoted by this title was subsequently ascertained by a specification enrolled in Chancery under a proviso to that effect contained in the patent. Of course such specifications constantly varied — and sometimes fraudulently — from what the inventor had in his mind when his application was made and his patent granted. For when he came to prepare his specification he was preternaturally wise with that wisdom which comes after the event. To meet this difficulty the draughtsmen of the 1852 Act devised the provisional specification, which was to be an amplified title, describing, with all the fulness necessary for complete identification, the invention for which the grant was made. By these and a number of subordinate improvements the British Patent-law was brought into a shape in which, though modernised in all its aspects, it provided adequate expression for the ancient common law as it had been formulated by Popham, C.J., and the Judges of the Queen's Bench, proclaimed by King James and finally ascertained by Sir Edward Coke and the drafting committee over which he presided in the Parliament of 1623.

The Patent Act of 1852 furnishes the high-water mark of English legislation on the subject of patents. It was by no means final. The scheme of Imperial legislation, of which it formed a part, required for its fulfilment the Colonial Patent Registration Acts, which actually followed in due succession. It required also that at some later date the registration system should be extended so that when the Colonies came to have fully equipped and organised patent offices of their own the practice of registration might become reciprocal between all the different members of the Empire, and a patent taken in any one part of the dominions of the Crown might confer certain inchoate rights in all parts of the King's dominions, rights which might be matured and taken up at the patentee's convenience as his business resources grew. The opportunity for a grand development along these lines occurred in 1883 when the next measure of Patent-law reform was taken in hand. But the opportunity was missed. An Act was passed which indued many old things with new names and introduced one conspicuously abortive change into the law. But by 1883 the spring of ideas had run dry, the useful alterations then made were insignificant, and

a form of statute was minted which, being adopted by most of our self-governing Colonies and larger dependencies, put an end—for the time, at least—to all developments in the direction of drawing the Colonies closer to the Mother Country, and corroborating the loose ties by which Greater Britain is held together. No attempt was made to facilitate the registration of British patents in the Colonies, or to give the holder of a Colonial patent any privilege on an application for a British grant. The scheme which had been carefully elaborated by the statesmen assembled from every part of the Empire—at a time when the British nation at home and oversea was profoundly conscious of its essential unity and imposing strength—was ignored thirty years later, possibly even forgotten altogether, for the Act of 1883 appears to have been the work not of statesmen but of draughtsmen. Unfortunately the example so set was widely and consistently followed. Colonial Patent Acts on the model of our own Act of 1883 followed in quick succession and have abolished the registration system everywhere except in Barbados, the Straits Settlements, and two or three other Colonies.

The place of the destroyed system is now being taken, but very inadequately filled, by the International Convention. This Convention, as you know, was originally drawn up for the purpose of facilitating what may be roughly described as an interchange of patent rights between a singularly heterogeneous assortment of States having no political union whatever. The signatories represented the kingdoms of Belgium, Spain, Italy, the Netherlands and Servia, the French Republic, the Republics of Guatemala, Salvador, and the Swiss Confederation, and the Empire of Brazil. By later accession our own country and some others have come into the treaty, and among our colonies, New Zealand, Queensland, Tasmania, Western Australia, and Ceylon, have adhered to the arrangement. This treaty, no doubt, effects as much as can be effected in the direction of facilitating patent grants to foreigners, and assimilating systems of jurisprudence so divergent in their nature as the Roman Dutch law and the Code Napoleon. By the irony of fate it is replacing in our own domestic system the family arrangement set up, but left necessarily imperfect in 1852, and as it comes into effect is reducing our Colonies one by one to the same footing in this respect as foreign countries. Since time does not permit me to discuss this matter at large, I will not enter upon it further, but in turning away from it I trust that I may be allowed to say, with the emphasis of a personal conviction, that it is wise not to take for granted and without critical inquiry, that the newer is the better plan.

In the cursory sketch, which is all that I can this evening attempt of the course which reform of our Patent-law has hitherto taken, there is not much that I need add, but even a cursory sketch would be incomplete without some reference to the Act of 1902, which has crowned and completed the work of 1883. The Act of 1883 introduced, as you know, a system of compulsory licenses, that is to say, of licenses which patentees might in certain cases be compelled to grant, in order to secure the establishment within the realm of industries protected by patent grants. The mischief which was aimed at by the measure is a curious one. That a patentee should obtain a patent grant for the purpose of enabling him to set up a manufacture here and then hang back from manufacturing, and even prohibit the establishment of the industry which he has undertaken to promote, seems on the face of it a ridiculous situation; a situation so ridiculous that it might not unreasonably be thought to be impossible. But impossible situations are constantly arising in practice and, in truth, the explanation of this anomaly is quite simple. There are, in fact, two perfectly distinct reasons for which applicants seek patent grants. One applicant desires to practice his invention and create by means of it a profitable trade, the profit of which shall in the main accrue to him. Another desires, not to practice trade, but to control it. He is quite content that other people should do the trade provided that he is privileged to lay a tax upon it. If both succeed, the one secures profit—the other toll. Now the one whose property is in the toll is not of necessity concerned with the manufacture at all. It suits him equally well to obtain his toll from something else which he has not invented. And this can very often be contrived with but a fraction of the ingenuity in which inventors, as a class, are rich. It is especially easy in the case of patents granted for chemical processes where mere words count necessarily for much, and mere opinions even for more. The palmary illustration is the case, often told, of the Blackley Red Dye. A patentee, whom I will call B, invents and patents a brown dye stuff which turns out to be of no commercial value. People cannot be

induced to buy it. Consequently there is no profit in it, and in the hands of a patentee of the manufacturer class it is a worthless grant. But time passes. Another inventor, whom I will call L, invents another dye, a red dye, for which there is a great demand. There is a considerable resemblance from the chemists' point of view—although very little from that of the practical man—the dyer—between the two substances. Both are hydrocarbons, both are derived from coal tar, both contain sulphur. The chemists are strongly of opinion that in passing from coal tar to red dye L must have passed through what I may for simplicity call a brown stage. Nobody of course pretends that a brown dye emerged at any stage. But in the existing state of our knowledge it is quite conceivable that incidentally and momentarily in the manufacturing operation the red dye stuff passed through a brown phase. That is enough for the patentee who lies in wait to take toll. Neither he nor anybody else can find any profit in his own invention, but it is quite conceivable that L in the course of making something else incurs a loss by reason of it, for eminent chemists can be brought to opine that in making the valuable red he must needs incur the expense of incidentally, momentarily, and wastefully producing the patented brown. Here then, if a court can be persuaded to act upon the conjectures of eminent scientific men, is a manufacturer who is at last practising the manufacture of the brown dye and yet contriving to make a profit on his business, taken as a whole. Clearly he is a man who can pay toll. Why should he not pay?

You will think perhaps that there would be an obvious answer to that question inasmuch as the invention from which he derived the profit was his own: that if the patentee is entitled to a share of anything at all it must be a share of the incidental loss, which the theoretical use of the patented invention entails. But that would be very old-fashioned Patent-law, and it is not at all difficult to explain how an inconvenient alternative like that is at the present day evaded altogether. It has, you will remember, been assumed that our patentee for this occasion is not concerned with profit. Therefore he does not ask for profit and so avoids all discussion as to the amount of the profit to be divided, or the source from which it comes. He asks the court to give him—not profit—but control. In the language of the law he asks for an injunction to restrain the manufacture of which he complains, and if the court will give him that, he willingly undertakes to manage the rest for himself. The audacity of such a demand is bewildering to anyone who stops to consider what it means.

An injunction is a legal contrivance for changing an unlawful act into a crime. The difference is well recognised in our law, and indeed in all civilised systems of law. For instance, it is an unlawful act to leave a just debt unpaid, but we do not now arrest the debtor, and clap him into gaol. He is constrained by gentler means to satisfy his creditor. Since the year 1869, our Legislature has carefully and consistently refrained from rating the defaulting debtor as a criminal at all, recognising, with a wise discernment, that the penalties of crime are not appropriate to all forms of shortcoming.

The rule of the Legislature was at one time the rule also of our courts. It was said that the remedy of injunction was an extraordinary remedy to which recourse should be had only when less stringent methods of coercion were shown to be inadequate to the requirements of the case. So lately as 1878, Lord Cairns laid down the rule that, in certain cases—the particular case with which he was dealing being a breach of covenant—a court of equity will see that by interposing, instead of leaving the parties to their remedy in damages, it would be doing more harm than it could possibly do good, and that in such a case it will take account of various incidental matters.

"It will consider, for example," said he, "whether the injury which it is asked to restrain is an injury which if done cannot be remedied. It will consider whether, if done, it can or cannot be sufficiently atoned for by the payment of a sum of money in damages. It will also ask this question—suppose the act to be done would the right to damages for it be decided exhaustively, once and for all, by one action or would there necessarily be a repetition of actions for the purpose of recovering damages from time to time. Those are matters which a Court of Equity would well look to and, on the other hand, a Court of Equity would look to this. If we interfere and say, in aid of this affirmative convenant that something shall not be done which would be a departure from it no doubt we shall succour and help the plaintiff who comes for our assistance. But shall we do that? Will the effect of our doing that be to cause possible damage to the defendant very much greater than any possible advantage we can give to the plantiff. Now, in a case of that kind where there is an amount of discretion which the court must exercise those are all considerations which the court will carefully entertain before it decides how it will exercise its discretion."

The case that we are considering is pre-eminently a case for the exercise of discretion. The patentee usually desires more than he is entitled to obtain in the way of relief even if his complaint of infringement be well founded. For argument can hardly be necessary to prove that profit and not control is what sound policy assigns to an inventor and what in fact a British patent is intended to convey to the patentee. There is a great risk that by the injunction, the court may give to him not profit but control. There is still another reason for caution. It is a principle of our law, as the passage just cited shows, that when the real matter of controversy is a breach of contract the courts will be somewhat slow to interfere by injunction and turn the mere breach into a crime. It would be easy, were this the proper place, to show that the wisdom of that rule is no less conspicuous than its mildness. Now the principle of the rule applies to the case of a discussion about the infringement of a patent right. At worst it is a breach of privilege; it can hardly be contended that the privilege is more sacred than a contract. In fact, the privilege itself has been described upon high judicial authority as a species of contract between the public and the patentee. For such a breach there is—special circumstances apart—an effectual and sufficient remedy in the awarding of damages to be paid by the infringer to the patentee. In that way the patentee comes by his own, that is to say, the profit of the invention. Of course, there may be cases in which the infringer is obstinate and irresponsible, will not regulate his conduct by the judgment of the court, and cannot be made to pay for his default. A case like that, no doubt, calls for the extraordinary remedy, and if an injunction makes such a defendant liable to imprisonment for a repetition of his breach, that would be entirely in conformity with the whole spirit of our law. But that, in fact, is not what happens. I do not suppose that there is a Judge upon our Bench who ever had to consider an application for an injunction based upon the ground that the infringer acted with knowledge that what he was doing was unlawful, or was persistent in his acts of infringement, or was an irresponsible person who could not be made answerable for damages and costs if these were awarded against him. Arguments like those would be treated as superfluous at the present day. The Act of 1852 gave to the courts a large power to grant injunctions in patent actions, a power which was still further enlarged by the Act of 1883. But whereas in 1852 the power was exercised with discrimination and more or less upon the principles just discussed, the courts now think it always fit to grant an injunction as part of the ordinary remedy in an ordinary case if the plaintiff succeeds.

You will now have no difficulty in perceiving how this new practice of the courts is exploited by the toll-collecting patentee. In the Blackley red case, for example, there was no question as to the extent of the injury suffered by the patentee, or whether he had suffered any injury at all. The fact that neither he nor anybody else could make a profit out of his manufacture did not enter into the reckoning, in fact there was no reckoning at all. The court was satisfied that the invisible, intangible, instantaneous brown stage in the red dye manufacture was infringement, and violated the patentee's exclusive right to make a loss by working the patented invention. So an injunction issued to restrain that improvident proceeding on the part of L, and incidentally, to restrain also his working of the very profitable manufacture of the red dye stuff which was his own invention. The commercial result in the case which I have mentioned was a great calamity, for not only did the control of L's invention pass into B's hands, but a large dependent dyeing industry passed bodily from Lancashire to Holland. The Lancashire dyers were compelled to allow the trade to pass into the hands of Dutchmen, for they were unable to obtain the dye either from the man who had invented, but was restrained from making it, or from the man who controlled the manufacture, but refused to supply it to them on equal terms with more favoured customers abroad. Thus a patent in which there is not a pennyworth of profit may be made the instrument of an extortion by which a prosperous trade, to the establishment and prosperity of which the patentee has contributed nothing whatever, may be reduced under his control, and taxed or destroyed for his emolument or for the consolidation of his grip upon our trade.

There are other ways in which a patentee can extend his privilege to the control of a trade which he has not himself either created or improved. He may, for example, be the patentee of an improved form of mantle for incandescent gas lamps. His mantles may be so highly efficient as to be in great request. But he may think that he would like to monopolise not only the trade in his own mantles, but also the trade in gas burners of the Bunsen type. If so, it is quite a simple

thing for him to sell his mantles with a condition that they shall only be mounted upon Bunsen burners bought from him. In a case like that the law was actually laid down in the year 1895 by a Judge of the Queen's Bench Division in these terms :—

"The patentee has the sole right of using and selling the articles, and he may prevent anybody from dealing with them at all. Inasmuch as he has the right to prevent people from using them or dealing in them at all, he has the right to do the lesser thing—that is to say, to impose his own conditions. It does not matter how unreasonable or how absurd the conditions are."

I have quoted this judgment textually because I should not hope, had I ventured to paraphrase it, to escape the suspicion of having travestied the doctrine of the Court. It is, perhaps, open to me to add that, although somewhat strongly expressed, this dictum may be taken to be substantially in accordance with the prevailing judicial view at the present time, so that an argument founded on the provisions of the statute law and of the patent grant itself for protecting the free industries of the realm, and preventing hurt of trade and inconvenience to the public, falls upon deaf ears when addressed to English Judges.

This encouragement afforded to patentees to exercise their ingenuity in preying upon other people's trade, has, of course, borne fruit, not only in one or two, but in a great variety of ways in recent times. One of the most subtle and, as I venture to think, one of the most dangerous by reason of its subtlety, may be illustrated by the following imaginary case. A patentee, whom I will call S., invents a sewing machine suitable for the manufacture of shoes. It is an excellent machine, and greatly cheapens and improves the manufacture. He takes a patent, and, being a man of capital, sets up the manufacture of his own machines. So far all is well. He is carrying out precisely the object for which the patent was granted to him. But on the principle that he may attach any conditions, however unreasonable, to the use of his invention by the public he refuses to sell his machines when made, and will only let them out on hiring agreements. Into these agreements he introduces conditions as to the purchase of thread and other materials, which enable him to create a business in those commodities, which is restricted to himself, and so, little by little, to build up a system of tied houses in the shoe trade. If his machine is good enough it will, of course, enable his dependents to beat other manufacturers in the competition of the market, and will eventually place the lucky patentee in such a position of financial control that the whole trade will have to do his bidding. Ultimately, when his patents lapse, it will be found that his business position is so strong that he will be able to take the profits of the shoe manufacturers just as a brewer takes the profits of the innkeepers whom he puts into his own public houses. When that stage is reached there will of course be, no further improvement in that trade. The original inventor has no motive to invent further even if he is still able so to do, and it is his business to see that no other inventor shall poach upon his preserve. The first advance was real, the initial advantage substantial, but the doctrine that a patentee is entitled not only to the profit, but, also, to the control of trade, is a ruinous doctrine in the end, and leads to that melancholy issue that "one good custom should corrupt the world."

I will ask you to bear with me if I advance yet another case in illustration of this point and of the many aspects which it wears, although I am very conscious that I must not consume your time this evening with the mere recital of facts. In this case, however, the recital will be more than mere fact, for the facts themselves sufficiently appear from the judgment which I propose to cite; and again, lest I should be suspected of inaccuracy, I will cite the judgment by the textual quotation of the important parts. The judgment was delivered so lately as July, 1904, and deals, not in general propositions merely, but expressly and in terms with the point which we are now considering. It expresses, therefore, in the most pointed and authentic form the law with which Patent-law reformers have to deal:—

"The case raised by the defence," said the learned Judge, "is one of a most unusual character. Each patent is admitted to be useful; it is admitted that the invention is properly described in the specification; it is admitted that there is no anticipation. Therefore, so far as the ordinary grounds upon which the question of validity or invalidity is discussed in this court, it is admitted that the patents are valid. But the defendants raise this defence, which I will state shortly without reading the particulars of objections. They say the patentee never intended to manufacture, and does not manufacture, the dye-stuffs in this country, and makes use of his patents to prevent other persons from doing so, and they say further that he makes use of the privilege granted to him by the patents—to put it shortly—by selling the dye-stuff at an exorbitant and unreasonable price,

and to the serious disadvantage of our people, as compared with the people in certain other countries in which the dye-stuff is sold at a lower price.

"So far as the facts are concerned, I have this: The plaintiffs have never manufactured in England. The ground which they put forward as a reason for their not having manufactured in England is that alcohol forms an important element in the manufacture of this product, and that the excise laws in England impose such a duty upon alcohol as that the manufacture cannot be carried on at a profit in this country. Whether this reason be a good or a bad one does not really concern me, but at all events, it is not an unreasonable one, and it commends itself as having some reasonableness behind it. I think I must infer, also, that from the first they never intended to manufacture in this country. I have it also proved that the dye-stuffs are sold in this country at a price considerably higher than that at which they are sold in certain other countries, and in particular I will take Switzerland as an example. But it happens that in Switzerland and, as I gather, in all other countries in which these dye-stuffs are sold at a price considerably under that at which they are sold in this country, there is no patent protection for chemical products, and so the plaintiffs have to suffer from competition, and the consequence of that is that they are compelled in those countries where they have competition to sell at a lower price. So also in certain countries where they have protection they are exposed to more or less infringement, and according as the infringement is more or less so again in those countries they are driven to make their prices lower or higher. Certain examples were given at a period some years ago, when the stuff in this country was sold at 30s., and the infringing material was sold at 15s. I am asked to infer from a comparison of these prices that the price charged by the plaintiff company was such an exorbitant and unreasonable price that on that ground alone the patent ought to be declared void or revoked. I cannot on these facts come to any such conclusion. There may have been various circumstances affecting the manufacture of the patented article which determined the price, and it is impossible for me on the facts, therefore, to come to the conclusion that the prices at which they have sold are so exorbitant and unreasonable as on that ground, assuming that the case of The King v. Eyre—and I only assume it for the moment—is a general anthority for the invalidity of a patent where the patentee makes use of it by charging an exorbitant and unreasonable price—assuming that to be an authority in the present case, I cannot on the facts come to the conclusion that the present case falls within that authority.

"Am I to refuse to give the plaintiffs relief on the other ground, which is the ground mainly put forward . . . namely, that the patentee did not intend to manufacture and does not manufacture the articles in this country? It is put in this way. It is said that *primâ facie* all monopolies are bad in law, that at the common law a monopoly was good if it was for the introduction of a new manufacture into this country by which employment was increased and the general prosperity of the country was contributed to."

The learned Judge then proceeded to discuss the authorities for this contention, and arrived at the conclusion that such a condition was not essential to the validity of the patent, which he accordingly upheld.

In order not to break up the statement of the case I have advanced beyond the year 1883 in my narrative, but that will not, I hope, cause you any inconvenience, for in asking you now to carry your minds back to that year I am not asking you to shut your eyes to what has since occurred. These later developments only exhibit in its mature plumage a mischief which was a fledgling in 1883 and while, therefore, it would be unfair if we were seeking to cast blame upon the legislators of that time to dwell on facts which could then only be discerned in embryo, it is otherwise on an occasion, like the present, when we are concerned with measures and not with men. The inadequacy of the measures then adopted can be better understood in the light of subsequent events.

It is then in the light of these fuller illustrations that you should consider the clause introduced into the Act of 1883 for dealing practically with the case of obstructive patents used by their owners either mainly or incidentally for the destruction or injuring of our trade. The clause forms the 22nd section of the Act and gave power to the Board of Trade to make an order in a proper case directing the patentee to grant a license under his patent upon terms settled by the Board. It was provided, and this provision proved in the end fatal to the scheme, that the section should commence life with a period of hybernation, for a saving clause exempted all then existing patents from its operation. Thus at first, and for many years, there was nothing for the section to operate upon, and when at last some bold adventurer proposed to set it in motion he found his task like that of waking the sleeping beauty. Nobody knew the way, and his path was obstructed at every step by a rank growth of thorny obstacles, the outcome of misappropriated time. It is not so that practical legislation originates, and if no other cause had intervened this alone would suffice to explain the abortive attempt at remedial legislation. But, in fact, another and more serious defect hampered its operation. The tribunal selected was not appropriate for deal-

ing with that particular matter. I do not mean to suggest a want of competence and even of special competence in the Board of Trade. Far from it. When eventually the jurisdiction came to be exercised, it was in fact, confided to very competent hands and administered in a manner which gave little ground, so far as I can understand the matter, for complaint. Substantially what complaint was made was a complaint concerning expense, but that is a matter which neither Parliament nor the tribunal could control. Commercial men fighting about their commercial interests are keen to get the best professional assistance, cost what it may. For this reason proceedings touching their interests, whatever their form, are expensive, and I suppose it will be so so long as there is a fashion in lawyers. I have never yet heard of a proposal by which the settling of terms of license between hostile parties could be rendered inexpensive or even materially cheapened.

The weakness of the tribunal arose from this fact, that it could only deal with a part of the matter in controversy. The demand for a compulsory license only arises when a manufacturer is threatened with a patent action, and if he has then to carry on litigation in two courts, his case is of necessity very hard. His defence in an ordinary case is really threefold:—1. Your patent is bad. 2. Even if good, it does not cover my manufacture. 3. Even if wrong under heads 1 and 2, I ought not to be restrained, but only compelled to pay you a reasonable royalty. Now, it is an old maxim of our law that "Circuity is to be avoided." To send litigants first to the High Court to get an injunction, and then to the Board of Trade to get rid of it was the worst possible form of legislation, tending to confound confusion and multiply expense. Since the first and second issues could only be decided in a court of law, the third ought to have been remitted to the High Court also. The whole controversy would then have been disposed of at one trial, and the question of the license decided without additional expense. It is no matter for wonder that an enactment so wholly at variance with elementary principles of legislation should have miscarried in the result. It contained a promise of relief, but a promise only, which must be redeemed, if ever, by means of some more workmanlike Act of Parliament at some future time.

A show was made of redeeming that promise three years ago, when the Patent-law Amendment Act of 1902 was passed. One principal subject of that Act was the grant of compulsory licenses, and, as in 1883, so in 1902, there was much shuffling of words with the idea of improving the expression of what had come to be the settled law. These amendments were probably not intended to have much effect, and certainly could not have effected much in the way of change in the substance or operation of the law. But in the report of the Departmental Committee upon which that Act was founded, and in the Bill, as originally presented to the House of Commons, was one provision which would have been revolutionary, and, like the true lover's kiss, have awakened the sleeper to youthful life and activity. It was at first proposed that the jurisdiction in matters of compulsory licenses should be transferred to the High Court. On second reading, however, the Government of the day withdrew that proposal, and for the High Court substituted a composite tribunal—the Board of Trade for preliminary investigation, and the Privy Council for final decision and settlement. This was "circuity" with a vengeance. Under the Act of 1883, the Board of Trade if satisfied with the *primâ facie* case made out by the applicant, could at once appoint a referee who would deal with the case forthwith and, save for the great defect which has just been pointed out, this was a perfectly satisfactory procedure. Certainly in respect of expense and expedition it was all that could be reasonably asked. Under the Act of 1902, the Board of Trade if satisfied as to the *primâ facie* case must send the applicant to the Judicial Committee, the most expensive court of first instance in the realm, and the Judicial Committee, if satisfied in turn with the applicant's case, must send him to a referee for the discussion and settlement of terms with the possibility of another hearing, and further argument upon the consideration by the Committee of the referee's report. To do justice to this method of amending the law, one must have recourse to something like Rehoboam's truculent threat, "My little finger shall be thicker than my father's loins." You did not greatly wonder that the Act of 1883 failed. You can hardly wonder more that the Act of 1902 has proved abortive.

But in truth it is not merely in respect of machinery that these acts are inadequate. If you consider them in the light of the mischief, as you can now see it, which they were intended to remedy, you will perceive that at the best a compulsory license does not deal with more than a small part of the case. Take, for ex-

ample, the mischief of the tied-house system. The sufferers are not competitors with the patentee in his own trade. In the case which I put before you, by way of illustration, they were bootmakers and he was a maker of bootmaking machinery. Why should a bootmaker want a license to make sewing machines? What he wants is the opportunity of buying them. A mere license to make or to use will not afford him the chance to buy, and for this case no form of license can afford a remedy. So again with the man who wants to furnish his existing gas burners with a new mantle. He is in no difficulty about the license, what he wants (and reasonably wants) is the opportunity of buying at market price. A compulsory license, if it can be had under reasonable conditions, may meet a case like the red-dye case, but that is only one of many forms which the mischief takes and therefore something more is wanted. What is that something?

To this question two answers have been proposed, and both, as I venture to think, are worthy of your careful consideration at the present time. The first has been much under discussion for several years past, and is to the effect that every patentee should be by law required to bring his invention into use, or to work his patent, as it is phrased, within the realm. This is perhaps proposed rather as an alternative to compulsory licensing than as a supplementary measure, for it is evident that it is, no more than that other, a remedy for the "unreasonable conditions" of use which our courts have so emphatically sanctioned. The tied-house system and the unreasonable license system would flourish no less than at present under a system of compulsory working. But for a part of the mischief, that is to say, for the injury inflicted on our trade by patentees who use their patent right to restrict the British market to goods manufactured abroad, it would afford a remedy. This mischief is in fact a very serious one; so serious that it is not at all surprising that on the part of commercial men it should have been considered apart, and to the exclusion of those other injuries which are less apparent to a cursory survey of the subject.

The argument is that it is the patentee's business to introduce his manufacture, and it is right that on him should be cast the burden of starting the business himself or of finding a licensee to start it for him. "Therefore," say the advocates of this measure, "shift the burden from the applicant for a license and turn the patent-holder into an applicant for a licensee. That is the logic of the situation if patents are granted for the purpose of establishing new manufactures within the realm." This contention appears to be broadly sound, but the principle is a little difficult of application. There are, for example, many patents granted for meritorious inventions which, nevertheless, it is not desirable to have worked within the realm. Let me give you, by way of illustration, the original patent for the incandescent electric lamp. The patentee described some five or six different ways of making the carbon filament which was the essential feature of his lamp. But improvement followed hard upon the heels of his invention. Before his patent could be exploited in this country he had himself invented an improved filament so much superior to those at first proposed that they at once became obsolete, and were never, in fact, manufactured at all. In such a case it would be childish to say: "You must plod on with the manufacture of inferior filaments, for which there is no use, in order to maintain your master patent." Take another case, which must be put in a hypothetical shape, although based on materials supplied by a lecture delivered at the Royal Institution last season by Professor Silvanus Thompson. Suppose, then, that some inventor were to devise a way of producing nitrate of soda from the nitrogen of the air. Suppose that this method could be carried out in Norway, where water power is abundant, so as to produce nitrate in unlimited quantity at a cost less than the present cost of South American nitrate. That would be a matter of capital importance to the British grower of wheat. A patent for such an invention might prove of the very highest value to the farmers of this country. But it may well be that if you were to require the patentee to carry on his manufacture in this country, where water power is small and not very available, the industry would be stifled, for the cost of nitrate manufactured by steam power might well be prohibitive. Such cases might be multiplied indefinitely, for, although generally true, it is by no means always true that manufacture beyond the realm of a patented article is an injury to British trade. The requirement of compulsory working is, therefore, one which needs to be imposed with carefully-considered limitations; but, given a rule elastic enough and equitable in operation, there is no doubt that for certain mischiefs it would be a remedy. And there is no reason to suppose that such a rule cannot be framed.

The other answer which I have to bring under your notice is more far-reaching and intended to go to the root of the matter and to deal with the mischief as a whole. You will have observed that all the schemes which predaceous patentees have elaborated for obtaining control of trade turn upon the injunction. The man with a patent for brown dyes captured the trade in red by means of an injunction. The man who tried to make the householder renew his gas fittings relied on an injunction to restrain the use of his mantles except upon terms of his own imposing. The man who planned a tied-house system of shoe manufacture could refuse to sell or even to let, except on his own terms, because he knew that the court would restrain by its injunction any breach of the conditions which it suited him to attach to the use of his machines. The foreign manufacturer who doubled the price of his goods to his English customers and diverted their dyeing industry to other countries was able to do so because the court by its injunction made the importation of that patentee's own goods from dealers in Switzerland, to whom he himself had freely sold them, a crime punishable by imprisonment at the discretion of the court. It is an injunction granted as a matter of course and without any regard to such circumstantial matters as those mentioned by Lord Cairns, granted without any regard to the convenience of the public or the hurt of trade, which is in every case the source and immediate cause of all the harm. Damages, the old common law remedy for infringement of patent right, suffice to secure to the patentee his profit—all to which he is in reason and sound law entitled, but give him no control. Damages in the red dye case could at the most have amounted to no more than a nominal sum, for actual damage there was none. But the control given by the injunction cost the Lancashire dyers thousands upon thousands of pounds. So with the other case. How ridiculous a patentee's complaint would sound if he asked for damages because a customer, who insisted on buying mantles at their full market price, refused to buy from him burners which he, the customer, did not want, and he, the intending seller, had not patented. So stated, the matter is unmistakably clear, the reason of it shines out, the unreason of it is manifest flagrant. But when the injunction is asked for and granted as a matter of course, and of ordinary relief, it all becomes inscrutable. Argument falls on deaf ears when Judges can declare that a patentee is entitled to press his privilege, however unreasonably, agains the public. It is the negation of all rule. In place of law we have the Roman lady's despotic maxim, "Sic volo, sic jubeo, stet pro ratione voluntas."

This proposal, then, is simply that the older practice with regard to the injunction should be restored; that the mischievous clause which says "that in an action for infringement, the Court or a Judge may . . . . make such order for an injunction . . . . as the Court or a Judge may see fit" should be repealed; and, in place of it, that the law should be laid down once more in the sense of the rule laid down in the still unrepealed clauses of the Statute of Monopolies, and now neglected only because the abolition of the Star Chamber has made the meaning of that old statute somewhat obscure, and the growth in recent years of the practice of granting injunctions without regard to incidental consequences has dethroned reason in our courts of law. The mischief has now gone so far that a remedy must be sought at the hands of the Legislature; and I venture respectfully to suggest for the consideration of the Society of Arts whether it is not fitting, at a time when Patent-law reform is being officially taken in hand, that the principles upon which this terrible jurisdiction to grant injunctions ought to be administered should be carefully considered by the Legislature and accurately defined by the authority of Parliament itself.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said the paper was not only a criticism of the existing law, but an extremely interesting historical *résumé* of the growth of Patent-law in this country. No doubt many had heard with surprise that Patent-law was indigenous to England, and that English law had been the root of all Patent-laws in every other country. It was also surprising to learn from the author that, from the days of James I., in 1623, to the days of Victoria, in 1852, no attempt had been made to reform the Patent-law. It must, however, be remembered that in 1851, as the author had pointed out, one of the greatest events in the industrial history of Great Britain happened, namely, the Exhibition of that year, promoted by the then President of the Society of Arts, the Prince Consort. Personally, he had been a good deal concerned with patents. His first patent, relating to duplex telegraphy, was taken out in 1853, so that he had long experience as a patentee of the working of the Patent-laws, and his experience of the taking out

of a patent from a commercial point of view was that it was worth less. He did not think he had ever made any money from any patent he had taken out, although his name figured pretty abundantly among patents, the reason being that while the law controlled the taking out of patents, finance and commerce settled the profit a patentee would obtain from them, and the two did not always agree. The author had stated that, however well the Act of 1852 worked until 1883, from that date up to the passing of the last Reform Act of 1902, confusion had followed instead of assistance to the public and the patentee. The author had certainly made out a very good case that the reform of the Patent Acts should be taken into very deep consideration by the Society of Arts. The subject was brought before the Council of the British Association in 1901, and a committee formed to consider it, but it was thought better to wait and see the operation of the Act of 1902 before troubling about any further reform. One curious feature in the paper was that while the law itself was pronounced by the Judges of the land, they had nothing whatever to do with the enactment of the law. A Bill was brought forward generally by a Department of the Government, after consideration in committee; a new Act was passed, and it was only when it became law that the Judges had to pronounce an opinion on it. It seemed only common sense that in the passing of an Act requiring the judgment of a Bench of Judges, a committee of Judges should be in existence which would take into consideration the accuracy of the enactment of new laws. The subject was of intense interest, and would no doubt produce an excellent discussion, and if the necessity should arise he would be prepared to consider the advisability of adjourning it to a future meeting.

Mr. Ivan Levinstein said that on the whole he entirely agreed with the author's paper, although there were a few points to which he took some exception. In the first instance, he would like to know how the travesty of justice had arisen in connection with the law as it originally stood. The author had not fully explained how it came about that the legal decisions were in absolute opposition to the law which still existed, a law laid down by the Statute of Monopolies. The State gave an important and most valuable asset to the patentee, viz., a sole and exclusive privilege, and naturally expected some service in return. The Legislators of James I. enacted that the sole and exclusive privileges were given on the condition that a new manufacture was introduced into the country in order to find work for its people and to generally benefit trade. How the travesty of the original law had arisen was perhaps difficult to say, but he thought it had been occasionally due to clever counsel and accommodating experts who had bamboozled the court to such an extent that at the finish of the case, the Judge knew less about it than at the beginning. The deputation which had recently waited upon the Board of Trade, and which was not solely represented, as the author appeared to think, by commercial men, but by inventors, learned societies, and more than 250,000 workpeople, asked the President of the Board of Trade to reinstate the law as laid down in the Statute of Monopolies, with several provisos. It did not ask that every patentee must work his patent, but that a patentee should only be called upon to work his patent in this country if he worked it abroad. A second proviso was that he need not be called upon to work it in this country if he justified his inaction to the satisfaction of the Board of Trade. There was a vast difference between those provisos and the simple fact that a patentee should be called upon to work his patent in this country; because it would be very hard to enact that, if a patentee did not do so his patent should be forfeited, inasmuch as the patentee might not have overcome the initial difficulties. It might take three, four, five, or six years to get a patent worked, and there was therefore great difficulty in fixing any term within which the patent must be worked. It would also be very hard that a poor patentee who could not get the necessary capital within a reasonable time should lose the benefit of his invention. In order to overcome these difficulties the resolutions which he had had the honour of moving on several occasions at the meetings of the Associated Chambers of Commerce, and which were unanimously passed, distinctly set forth that the patentee should only be called upon to work his patent in this country if he worked it exclusively abroad, unless he justified his inaction to the satisfaction of the Board of Trade. The author thought that the application of a law for compulsory working would create a difficulty, but the illustrations he had given did not bear out that view. There were very few patents indeed which could not be worked in this country which were worked abroad. Mr. Gordon had referred to the incandescent electric lamp case as one of his illustrations to prove the difficulty of application; but that example would meet with no difficulty whatever, because if the processes had not been worked abroad the manufacturer could not be called upon to lose his patent. With regard to the second illustration, the manufacture of nitrate of lime from the nitrogen of air, it might be of interest to state that a company had been formed in Germany with one million capital, which had been fortified with additional capital from France, so that the joint company would command a capital of four million pounds, for the production of nitrate of lime for fertilising purposes. The process was by no means confined to Norway, as it could be carried out in many other countries; but even that illustration would be fully met by the resolution of the Associated Chambers of Commerce, which contained the proviso that the patentee must justify his inaction to the satisfaction of the Board of Trade. If it was the fact that there was no water-power in this country, or that cheap fuel cou'd not compete

with water-power, there would be no difficulty whatever in proving to the satisfaction of the Board of Trade that the process could not be satisfactorily carried out in this country. He had, therefore, come to the conclusion that the author's carefully selected illustrations did not meet the difficulties he suggested in the application of compulsory working. This country had lost millions of pounds by its foolishness in not insisting on compulsory working. Eight thousand patents per annum were granted in this country to foreign patentees, and the only return they gave for that privilege was that they could impose the most intolerant and absurd conditions upon our trade as shown by the author. By working British monopolies exclusively abroad, our own workmen were thrown out of employment, whilst the patentee did not contribute a farthing to Imperial or local taxation. Not only were new industries thus established in foreign countries, but, worse than that, when the legal term of the patent had lapsed, in many cases there was no one in this country who could continue the process for which a British monopoly had been given. We possessed neither the machinery nor the men, and frequently did not know the process which the foreigner was carrying out—he referred chiefly in this instance to chemical processes—the result being that many of the monopolies which had been granted had become perpetual monopolies. The present Government had promised that they would introduce a Bill incorporating the principles of the Associated Chambers of Commerce resolution; if such a Bill were passed it would confer a real boon on the industries of this country, because there was no doubt whatever that new industries and new manufactures would be introduced. So far as the stability of trade in this country was concerned, one of its greatest disadvantages was that it relied chiefly on a few staple industries.

Sir JOSEPH LAWRENCE, after thanking the author for his excellent paper, said the Chairman had dwelt upon the drawbacks the Judges were under in interpreting Acts of Parliament passed by the Legislature without their having had anything to do with the framing of the Bills in the first instance. The difficulty he experienced in regard to the measure of 1902, which he assisted Mr. Gerald Balfour very considerably in carrying was, that they were legislating on the basis of a report prepared by a Departmental Committee which largely consisted of lawyers. He felt there was not a man on that committee who was practically and commercially acquainted with the working of patented industries, the result being that the great reform for which the commercial community of the country had been crying aloud for nearly 40 years was never touched in the slightest degree; in fact, the present Lord Chief Justice, who was a member of the committee, said when the question was raised, that the committee was not met to discuss the economic question. The terms of reference to the committee were extremely narrow, and excluded the questions which the commercial and manufacturing community desired to be discussed. For nearly thirty years, Mr. Levinstein had been agitating on the question at the Associated Chambers of Commerce and Chemical Institutions. He was the man who called attention to the prospective loss of the aniline dye industry, a great question which was not even referred to by the committee. The reformers were told by the lawyers that the matter could not be remedied, and even Mr. Gordon at one time held that view, but he was fast coming round to an opposite opinion. It had now become necessary for the laymen to tell the lawyers of this country what was done by the laws and legislatures of other countries. In this connection, he desired, to save time, to quote from an article of his own, which appeared in the October number of the *National Review*, as to what was being done in Germany, a country which was going ahead by leaps and bounds. He there said: "A long series of successful actions for the revocation of patents in Germany, on the ground of non-working, show that the question considered by the Courts is whether the Commonwealth has suffered, or is likely to suffer, by the neglect of the patentee to work his patent in the country. The law keeps the common weal in view in compelling the working of the patent in Germany. The production must contribute to the advancement of inland commercial industry. The articles protected by the patent must be produced in the country. The patentee cannot excuse himself from the legal obligation to work his patent by the plea that there is no remunerative demand for the patented article. Only *bonâ fide* efforts to work are of any avail; part of the work being done in Germany will not be regarded as working 'to an adequate extent.' In no case is it admitted that the patentee can delay working till he has a certain prospect of a market to recoup him for his outlay. As recently as April, 1904, a patent for stoppered bottles was revoked because, though the bottles had been made in Germany, the aluminium stoppers had been imported. One of the reasons given by the German Court is noteworthy. "Because aluminium is cheap in Germany, German industry as such has an interest in the patent being worked in this country.'" He quoted in the House of Commons the celebrated case of Gruson, of Magdeburg, who held a patent for armoured trains in France. The French officials contended that the two years within which he ought to have manufactured in that country under his patent had expired. The patentee replied that there was only one customer for armoured trains in France—the Government—that he offered the patent to the Government who, after considering it for eighteen months, declined it. Nevertheless, the French patent office confiscated the patent. It was untrue, historically and in fact, to say that compulsory working was not enforced on the Continent. It was enforced to such an extent that it was a colossal disadvantage to English industry. Five years ago Mr. Levinstein and

himself headed a powerful deputation from various Chambers of Commerce, representative of all shades of political opinion, to the then President of the Board of Trade with the object of amending the Bill of 1902, which was framed on the recommendation of lawyers, and he then stated that the Bill was an instance of the way in which English commercial industries were menaced by the present Patent-laws. The whole system of English Patent-laws had been overlaid by the subtleties of the law. He had a high appreciation of Mr. Gordon's enormous learning on the question of patents, because no man had devoted himself to the question with a higher sense of duty, singleness of purpose, and a profounder desire to remedy the present evils than Mr. Gordon had done; and if the author did not see absolutely eye to eye with Mr. Levinstein and himself, yet he had a strong eye for justice, and was gradually beginning to realise that they were not such fools as they had hitherto been represented to be by lawyers, and that good solid common sense was at the basis of what they were working for. He thought they could take some comfort from the results of their endeavours. For years they had been pegging away in the Associated Chambers of Commerce, with the result that two unanimous resolutions had now been passed recommending the policy which Mr. Levinstein had brought forward, namely, that where a foreigner took out a patent in this country and worked it in his own, he must come here also and work it in order to give employment to English people, which was one of the conditions upon which the original patent rights were granted. That followed a sound good policy, and it furthermore staved off very grave injustices which had been inflicted upon English people in the past. For instance, everybody knew the celebrated case in which Mr. Levinstein sought to get elementary justice by carrying the case to the highest court, and failed. People in Germany took out patents for manufacturing dye stuffs which vitally hit Mr. Levinstein's business; Mr. Levinstein unsuccessfully endeavoured to obtain a compulsory license, with the result that the German manufacturers seriously interfered with the trade of every chemical manufacturer in this country. Mr. Gordon set out very strongly the evils of patentees owning the control and profits, but suggested no remedy, only recommending very warmly a very pet view of his, namely, some restriction being placed on the power of Judges to grant injunctions. He did not think that people engaged in manufacture in this country were particularly anxious about that, and there had been no pronouncement upon the part of any of the public bodies of this country in favour of limiting that power. He knew of a recent case where the exercise of that power by the Judges had a just and wholesome effect. Some foreigners came over to England and introduced an industry, which was a gross infringement of an existing patent, and if they had been allowed to go on, the manufacturer, whose business was prejudiced, would not have had a bawbee left by the time he had taken all the necessary legal steps through the courts up to the House of Lords. In such a case it was a very wholesome power to keep unrestricted, and he thought the Judges might be trusted to exercise a very fair discretion, because they were men animated by a high sense of justice and fairplay. He would do nothing to restrict that power; in any case he would not lessen their powers of discretion. He frankly admitted that the Act of 1902 was a dead letter. They asked for the power of compulsory working, but were not granted it, the bugbear of the Convention being thrown in their faces. They were not asked as a body to give evidence before the Departmental Committee, and consequently their views were not known. On the occasion of the last deputation to the Board of Trade, he told the President that he did not desire to place any disability upon any foreign patentee which he, as an Englishman, was not prepared to submit to. Mr. Lloyd George at once said that that was the only point that had hitherto divided them, and agreed that they had absolutely made out their case, and, on a subsequent occasion, informed them that he intended to bring in a Bill on the lines the deputation recommended. There was, therefore, a prospect of what they had been fighting for for so many years, being realised before long, and he trusted they would have the loyal help and support of Mr. Gordon in the framing of the measure which would be brought before Parliament. A Bill had already been drafted and laid before the President of the Board of Trade which, he believed, would meet with the unanimous support of all parties in the House, of all the commercial and manufacturing community, and last, but not least, of the legal powers of the country. The difficulty he experienced in the House of Commons was that, whilst he had certain able patent counsel on one side supporting the commercial interests, there were other lawyers on the other side who were frightened to death to do anything to disturb the Ark of the Covenant. He told them it would have to be done, and by dint of hard work he thought they were in a fair way of getting it accomplished.

The CHAIRMAN announced that, owing to the number of gentlemen who were desirous of speaking, it had been decided to adjourn the discussion to Wednesday, January 16th, 1907, the first evening meeting after the Christmas recess.

THE CANADIAN FUR TRADE.

For more than two centuries, the fur trade has been vigorously prosecuted in Northern Canada, and yet the supply, save in the case of two or three varieties of animals, shows no great signs of exhaustion. The buffalo, whose hide was once an important article of commerce, has disappeared before the advance of civilisation. The beaver can apparently only be saved from a similar fate by extraordinary measures of pro-

tection; so too the fur seal of the islands and waters of the Pacific. Sea otter and silver fox have been rare for many years. What the home consumption amounts to, can only be surmised. According to the Canadian statistical returns, the export of furs to the United Kingdom and the United States amounted respectively to £297,000 and £131,000 in the year 1904. The total value of furs exported from Canada amounted in the year 1904 to £448,000. Besides Great Britain and the United States, France and Germany are importers of Canadian furs. Competition from such influential sources as the Hudson's Bay Company, working from Winnipeg; Revillon Frères (from Edmonton) and other extensive fur buyers maintaining posts all over the north, from Labrador to Mackenzie River and beyond, has according to the United States Consul at Dawson City, cut down the local trade in furs, and introduced arbitrary rates and precarious dealings, rendering trade on a small scale, hazardous. In Yukon Territory, the marten has recently migrated, owing, it is said, to the appearance upon the scene of unusual numbers of lynx. This condition is probably only passing and temporary. Fur buyers seem to agree that the fur-bearing animals of the north, with the exceptions noted, are not becoming extinct. Vast extents of territory still remain approximately virgin and unexploited, and the Indians are proving surprisingly careful in preserving the game. The Indians bring the skins to the various posts, and exchange them for merchandise; it is all a matter of barter. The standard of value in some parts is a beaver skin; in others, the skin of the red fox. In the interior of Alaska, the price paid for furs and supplies are regulated by the price of the red fox or of the marten, called one skin. London continues to rank as the principal fur market of the world, to which are shipped furs from Asia, including Siberia, Europe, and America. Subsidiary markets are Tacoma, St. Louis, Montreal, New York, Paris, Leipzig, Novgorod and Kiakhta. In the world's fur trade, Alaska plays no insignificant part. The exports of Alaskan furs for the twelve months ended June 30th, 1904, amounted in value to £93,000, and for the twelve months ended June 30th, 1905, to £103,000. Great quantities of furs are taken in Alaska, embracing those of the polar bear, black bear, brown bear, black wolf; white, red, blue and silver grey foxes, badger, beaver, sables and seals. It is known that Alaska has yielded great wealth to this industry, but the extent cannot be stated with any certainty, as it has been the policy of the fur trader to conceal his operations, and the conditions of the trade are such that he is able to do so. The annual collection of furs is a matter of ceaseless change. Fashion, fastidious and fickle, neglects the use of certain kinds of furs for a season, the market price of the pelt no longer repays the outfit of the trapper; the hunt is intermittent, and in two or three years the animal regains its numbers and strength. Owing to the steady growth in the demand for furs in nearly all countries, and also as a result of the establishment of peace between Japan and Russia—the latter country being generally a large consumer of furs—fur merchants appear fairly satisfied with the outlook, fearing no serious set back, provided fictitious boom conditions and inflation do not interfere.

THE EFFECTS OF TUBERCULOSIS ON THE FRENCH POPULATION.

The Academy of Medecine, at Paris, has been recently discussing the value of the official statistics regarding the mortality from tuberculosis in France. According to these statistics, 150,000 persons die each year in France from this disease. This represents 39 deaths, caused by tuberculosis, out of every 10,000; while in Germany, it is said, the same malady carries off only 22 persons in 10,000. This fact has led to a critical examination of French vital statistics, and, during the discussion at the Academy, many interesting facts have been brought out, showing the basis on which these statistics have been established. Definite information is received from only 713 cities and towns having a population of more than 5,000 inhabitants, making a total of 12,000,000 inhabitants, among whom the mortality from tuberculosis amounts to 42,000 per annum. This has served as a basis of calculation for the rest of the country that furnishes no reliable statistics, and to this is added the deaths from chronic bronchitis (approximately 50,000), making, in this way, a total of 150,000 deaths from tuberculosis. In Germany, it is stated, chronic bronchitis is excluded, and account is only taken of cases of tuberculosis proper, or even only of pulmonary tuberculosis. Allowance must also be made in both countries for errors in diagnosis. Indeed no malady is apparently so subject to being cut up, divided, and hidden away under various names and classifications in the statistics. According to the American Consular representative in Paris, Professor Albert Robin has established from the statistics of 1901, 1902, and 1903, that tuberculosis decreases in an almost regular proportion to the density of the population. He has accordingly compiled a table of deaths from tuberculosis in France during the year 1903, showing the percentage of deaths per 10,000 inhabitants to be 45·2 in Paris; in cities of 100,000 to 492,000 inhabitants, 34·4; in cities of 30,000 to 100,000 inhabitants, 32·8; in cities of 20,000 to 30,000 inhabitants, 30·8; in cities of 10,000 to 20,000 inhabitants, 26·6; in cities of 5,000 to 10,000 inhabitants, 23·4; and in cities of 1,000 to 5,000 inhabitants, 20·4. This calculation brings the rate close to the German average, and led Professor Robin to express his belief that the German system of popular sanatoria had less merit than public measures of hygiene and sanitation. A great many medical men, however, believe that even the French official figures are below the reality. Those deaths reported as from "unknown causes" amount to 28 per cent., and undoubtedly include many cases of tuberculosis. For instance, in ten of the principal country towns, out of 47,490 deaths, 10,178 were

classified under "other causes." In towns of medium importance, such as Roanne, out of 34,000 inhabitants and 723 deaths, the statistics indicate 74 deaths from tuberculosis, 342 from "other causes," and 20 from "unknown causes." It is much the same everywhere. At Nanterre, more than half the deaths were without any information as to causes. The consensus of opinion, therefore, would seem to be that it is almost impossible to make any serious deductions or comparisons from the official statistics as at present organised, owing to their incompleteness and, in some cases, inaccuracy. While some departments, like that of the Seine, furnish absolutely exact statistics as to tuberculosis, others do not furnish any at all. Another cause in inaccuracy is the evident lack of sincerity in declaring the cause of death. In certain towns, since the declaration of death from tuberculosis has been made obligatory, only persons in hospitals die from that disease; the rich die from bronchitis. So also in Paris, the death-rate from tuberculosis in the Champs Elysées quarter is only 10·5 to 11 per 10,000 inhabitants, while at Plaisance it amounts to 105. The campaign against tuberculosis in France has assumed such national importance that the French Academy of Medecine has very recently been discussing the necessity for the compulsory declaration of cases of tuberculosis by the doctor in attendance, but this has been met with a storm of opposition, as it is claimed that thereby a large number of consumptives would be deprived of all means of support, since no one would then knowingly have them in their employ. The question of the effect of certain occupations on tuberculosis has been carefully investigated in France, it has been found that those trades that bring persons into contact with dust, are especially dangerous. Professor Landouzy's investigations among policemen and postal *employés*—both of whom have very insanitary offices—indeed the public complaints against the impure air in post-offices in Paris are most frequent—and also among laundry workers, have revealed a disastrous condition of affairs. Also among 245 workmen, carefully kept under observation by Professor Landouzy, consisting of carpenters, joiners, floor layers, and packers, all living under practically the same conditions, the mortality from tuberculosis amounted to more than 30 per cent. Laundry workers, however, were found to be the most seriously affected. The Paris bakers, a short time ago, formed an organisation for the improvement of insanitary conditions under which they have to work. It is stated authoritatively that despite the governmental inspection of bakeries, and the most modern hygienic apparatus, large numbers of bakers suffer from tuberculosis. The State Department of Public Charities regarding this struggle against tuberculosis as a national and social duty, is considering the establishment of special hospitals for tuberculosis, both in Paris and throughout the country, where patients can be properly isolated, and given special treatment.

HOME INDUSTRIES.

The End of the Shipbuilding Strike.—The hope expressed in these notes on November 9th has been fulfilled, and the shipbuilding crisis on the Clyde is at an end. As demonstrated here more than once, the strike was predoomed to failure. It was a belated strike. A year or eighteen months earlier a case might have been made out for a rise in wages, but it was not submitted, and when the demand was made the employers said not only that the prospects of the trade would not warrant it, but that unless trade improved, it would not be possible to continue to find work for all the present hands. Under those circumstances concession to the demands of the strikers was plainly impossible. This has been so obvious that the trade unions as a whole had no sympathy with the strike, and regretted the obstinacy of the boiler makers, who, in the pursuit of ends that could not be achieved, brought privation and misery on other workers without their resources. If the strikers had not recognised the truth when they did there would have been a lock out—which would have added greatly to the distress. Fortunately the men were brought to see the facts of the situation in time to prevent the threatened lock out, and their unconditional surrender has ended the crisis. They have resumed work at the rates they were obtaining when they ceased work. Unfortunately, with the continuance of the present demand for steel and steel making iron, there is not much likelihood of shipbuilders securing many coutracts of importance for new ships during the winter months; and it must be expected, that there will be less and less to do in the shipyards as the work in hand is finished.

Railways and Trade.—The growth of the foreign trade of the United Kingdom during the last two years has been great. Exports have grown by 27 per cent, and imports by 9 per cent. It is less easy to gauge the home trade; exact data are wanting. It is notorious that the building trade has been slack, and the consuming trades are complaining. But as to trade generally, there is no better test of trade than railway earnings. They carry the raw materials for mauufacture, and the manufactured goods for shipment, or to the point for distribution; they carry the food for the maintenance of most of the people of the country, and convey all but local travellers from place to place. If the railways are active, if their earnings show satisfacfactory increase, then it is pretty safe to assume that the districts they serve have little to complain of as touching trade. If this test is a true one, then there is little to complain of in the present state of trade. In the first half of the present year the expansion in railway gross earnings was about 3½ per cent., and it may be assumed that for 1906 the growth of trade as reflected by railway traffic will be nearly 3 per cent. compared with 1905, or 5 per cent. as compared with 1904, a very satisfactory growth. The *Statist* of November 24th gives a very interesting table indicating the state of trade in

the current year, in contrast with that of 1905 and 1904, and in contrast with the usual rate of growth it gives a contrast of the receipts of British railways in each year since 1870. The growth in gross earnings over this period is very remarkable. In 1870, when trade was very active, the year, it will be remembered, that Mr. Chamberlain took for comparison with 1903, the gross earnings of the railway system of the United Kingdom amounted to £45,078,000; in 1905 they were £112,500,000, and in 1906 (the gross earnings of the December half being partly estimated) £115,500,000. In the present year the growth of trade, as reflected by railway traffic, will be nearly 3 per cent. over that of last year. The largest expansions in railway earnings in 1906, as compared with 1905, taking the first twenty weeks of the current half-year, are shown by the North Eastern, £243,000; North Western, £178,000; Great Western, £132,000; and Midland, £106,000, the exceptional increase of the North Eastern being explained by the great activity of the coal and iron industries in the north-east portion of England. It is estimated that the increase in the earnings of the nineteen principal railway companies during the current half-year will not be less than £1,300,000, but much of this will be swallowed up by the higher prices of material and coal and expenditure on improvements. The sum required to pay an additional dividend at the rate of $\frac{1}{4}$ per cent. upon the ordinary capitals of the nineteen companies is £323,000, and an average improvement in the dividend distribution of the companies of from $\frac{1}{8}$ to $\frac{1}{4}$ per cent. may be reasonably anticipated.

The Merchant Shipping Bill.—There are many clauses of the Merchant Shipping Bill which has now passed the House of Commons to which experts take exception, as for example the clause that practically deprives the local Marine Boards of the most important of the functions bestowed on them by the Act of 1854, but on the whole it seems to be the general verdict of instructed opinion that the Bill proceeds on the right lines, and should be of some considerable service to the shipping world. It is hopeful that on the whole the President of the Board of Trade, recognising that British shipping is our foremost industry, and that undue meddling with it might work irreparable harm, has worked with rather than in opposition to the shipowners. The clauses affecting seamen go some way to meet their complaints as to feeding and bunking, legitimate complaints that have had a good deal to do with the unwillingness of young men to "go to sea." That part of the Bill which relates to the application of British load-line regulations to foreign ships has been most keenly discussed, and it may be hoped that it will result in the only permanently satisfactory solution, namely, an international agreement. If it be true that the German Goverment are anxious to have their load-line defined on the same scale as the British, there ought to be no insuperable difficulty to the settlement of this vexed question before the amending Act comes into operation in 1908. The Government recognised that it was impossible to accede to the wishes of a considerable number of their supporters, and penalise the master or owner of a foreign ship for leaving a home port deeper than British regulations permit, it being only possible to deal with the load-line as it appears in British waters. Many will regret that the Bill does not deal in more drastic fashion with the foreign element in the British marine, but the question is much less simple than it appears to the layman. Still, a beginning has been made.

Cotton and the Empire.—The second annual report of the British Cotton Growing Association is very encouraging, and will be read with much satisfaction by those who recognise the importance of growing the cotton required by Lancashire within the limits of the Empire. It is a little strange that an Association having for its object this most desirable result, and supported and controlled by some of the most prominent men in Lancashire, should have failed to receive the public support necessary to the full subscription of its nominal capital of £500,000, only £247,000 having been subscribed. It may be hoped, however, that before long the whole of the balance will be found. The council urgently appeal for more capital to develop the cotton cultivation of West Africa, stating that the expenditure next year in that region will be £50,000, while in 1908 probably £100,000 will be wanted. The Council state they have every reason to believe that the loss on working, which has been greatly reduced, will be further reduced next year, and that in 1908 they will be able to show an even account, and possibly a profit. The report goes so far as to say that, "The time for experiment has passed. The case is proved. All the cotton Lancashire requires can be grown within the limits of the Empire." That is true, but we seem to be far from the time when it will be a fact. As the report admits, if the industry is to be made an absolute success it will require fostering for many years, hence the importance of the work of the Association, and of its obtaining the necessary funds to pursue its work. Details of the work accomplished in India and the several colonies accompany the report. In India, 20,411,000 acres are now devoted to cotton, and the crop in 1905-6 amounted 3,240,000 bales, but much of it does not come to England. It has been practically established that Egyptian cotton can be successfully grown in India, and Sind may be expected to supplement the Egyptian crop. Substantial progress has been made in the West Indies. Not only has the area under cotton largely increased, but the quality has been well maintained, and in many cases improved. The planters have obtained good prices, the better growths fetching 2d. to 3d. per pound over similar grades of American cotton. Four thousand and forty-two bales of West Indian cotton passed through

the hands of the Association in 1906, and realised £68,674, as compared with £28,331, for 1,746 bales, in 1905. In West Africa the progress has been very gratifying, and has exceeded the expectations of the council. In a year or two equally good results are looked for from Northern Nigeria to those already achieved in Lagos; on a smaller scale, too, the Gold Coast, Sierra Leone, and Southern Nigeria may be expected to contribute. The results of cotton growing in British Central Africa have not as yet been great, and in South Africa the Association has been unable to take any active steps, but advice and assistance have been readily given, and there is fair prospect of the establishment of cotton growing as a permanent industry. It will be seen that the Association is doing good work in many directions, but its efforts are still far from meeting the yearly increase in the world's consumption of cotton, and it must be many years before Lancashire's dependence upon the Southern States of America is materially affected.

The Drainage of Mines.—An interesting experiment is being tried in Cumberland in connection with the drainage of mines. Most of the iron mines in Furness and West Cumberland are heavily watered, and frequently, owing to surface drainage, the water finds its way, in some measure, into the workings again. Electric pumps have recently been adopted by a company owning large iron mines in Furness to deal with the water, and they are now engaged in putting the pumps down. They will not be handicapped with the ordinary pumping gear. All the power exercised on the motors will be used on the pumps themselves, and it is expected that not only will great economy result, but that when the new system is in full operation there will not be any need to close a mine when a breakdown takes place at the pumps, as it will only mean a sectional stoppage. The experiment will be watched with much interest by other mine owners in the district, and it is to be hoped that the results confidently anticipated from this introduction of electric power will ensue. If they do it will mean much to the district and others similarly situated.

GENERAL NOTES.

Coachbuilding Prizes.—The Company of Coach Makers and Coach-harness Makers of London offer the following prizes for competition among British subjects engaged in the trades of coach and coach-harness making, motor-body making, and accessory trades, and members of drawing and technical classes in connection with such trades, resident in the United Kingdom of Great Britain and Ireland. Competition No. 1 (open to all)—For drawings of a double victoria, without doors, for one or a pair of horses, to seat four persons inside; lever brake; side and half back elevations; scale 3 inches to the foot; 1st prize, the Company's silver medal and £4 4s.; 2nd prize, the Company's bronze medal and £2 2s. Competition No. 2 (open to all, except teachers)—For drawings of a small, light motor-car body, to seat two persons, suitable for a country medical practitioner; side elevation, half back, and half plan; scale 3 inches to the foot; 1st prize, £3 3s.; 2nd prize, £2 2s.; 3rd prize, £1 1s. Competition No. 3 (confined to coach and motor-body painters)—For the best specimens of painting, the whole of which from the priming to the last coat of varnish must be the work of the competitor; the specimens being one mahogany panel and one aluminium or pressed steel panel, surrounded with a flat moulding with a quirk and painted any colour, with or without black stripes, and twelve half spokes each to be twelve inches long, two painted crimson lake, two napier green, and eight of any colours selected by the competitor, all relieved by lines of suitable colours; 1st prize, £3 3s.; 2nd prize, £2 2s.; 3rd prize, £1 1s. Competition No. 4 (open to all)—The Master, F. Wykeham Chancellor, M.A., offers £10 10s., and the Company offer a silver medal and £7 7s. as below:—For drawings of a three-quarter landaulette motor-car body (*i.e.*, with light behind standing pillar), with wings and platform step, extension front and screen, to carry four persons in the body and one by the side of the chauffeur, the outline of chassis, wheels, levers and steering wheel to be shown; side view to be closed and half plan; scale 3 inches to the foot; 1st prize, the Company's silver medal and £10 10s.; 2nd prize, the Company's bronze medal and £5 5s.; 3rd prize, £2 2s. Competition No. 5 (open to those under 18 years of age who have never won a prize in the Company's competitions)—For drawings of a four-wheel station luggage cart, to carry two or four persons; side view; scale 2 inches to the foot; 1st prize, £2 2s.; 2nd prize, £1 1s. Competition No. 6 (open to all)—For drawings of six monograms, 3 inches in size, suitable for a carriage panel:—F.W.C., R.G.A., J.S.B., E.W.W., A.C., C.T.B.; 1st prize, £3 3s.; 2nd prize, £1 1s. The above prizes will be accompanied by the certificate of the Company.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday Evenings, at 8 o'clock:—

December 5.—"The Metric System." By Colonel Sir Charles M. Watson, K.C.M.G., C.B. Sir David Gill, K.C.B., F.R.S., will preside.

December 12.—"Fruit Growing and the Protection of Birds." By Cecil H. Hooper, Member of the Council of the National Fruit-Growers' Association.

December 19.—"Modern Developments of Flour-Milling." By Albert E. Humphries, President of the Incorporated Association of British and Irish Millers. Professor Thomas Hudson Middleton, M.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

DECEMBER 4.—"The Cape to Cairo Railway." By THE HON. SIR LEWIS MICHELL, late Member of the Cape Ministry. THE RIGHT HON. VISCOUNT MILNER, G.C.B., G.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

DECEMBER 13.—"The Indian Mohammedans: their Past, Present, and Future." By A. YUSUF ALI, M.A., LL.M. (Cantab.), I.C.S. LORD AMPTHILL, G.C.S.I, G.C.I.E., will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

DECEMBER 18.—"Basket-Making." By THOMAS OKEY. LEWIS FOREMAN DAY, F.S.A., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

A. D. HALL, M.A., Director of Lawes Agricultural Trust, "Artificial Fertilisers: their Nature and Functions." Five Lectures.

LECTURE III.—DECEMBER 3.—*Nitrogenous Fertilisers.*

JUVENILE LECTURES.

Two Lectures suitable for a Juvenile audience will be delivered on Wednesday afternoons, January 2 and 9, 1907, at 5 o'clock.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 3...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. D. Hall, "Artificial Fertilisers: their Nature and Functions." (Lecture III.)

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Messrs. W. Pollard Digby and C. H. Shenton, "Prevention of the Bacterial Contamination of Streams and Oyster Beds."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. H. W. Rowell, "The Direct Estimation of Antimony." 2. Mr. M. Wynter Blyth, "Bacterial Method of Investigating Disinfectants." 3. Dr. J. Gordon Parker and H. Garner Bennett, "The Detannisation of Solutions in the Analysis of Tanning Materials."

University of London, South Kensington, S.W., 8 p.m. Mr. Banister Fletcher, "Greek Temples of the Ionic Order."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. G. C. Haité, "Design and Designers of the Victorian Era."

TUESDAY, DEC. 4...SOCIETY OF ARTS, John-street, Adelphi, 4½ p.m. (Colonial Section.) Hon. Sir Lewis Michell, "The Cape to Cairo Railway."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussions on following papers:—1. Mr. W. A. P. Tait, "The Talla Water-Supply of the Edinburgh and District Waterworks." 2. Mr. M. Ratcliffe Barnett, "Repairing a Limestone-Concrete Aqueduct." 3. Mr. E. P. Hill, "The Yield of Catchment Areas."

Designers, 6½, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. Hugh Stannus, "The Korinthic Capital."

Tramways and Light Railways Association, Westminster Palace Hotel, S.W., 4½ p.m. General Meeting.

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Demonstration of Three-Colour Photography by the Rotary Photographic Company.

Anthropological, 3, Hanover-square, W., 8½ p.m.

Cold Storage and Ice Association, London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 7½ p.m. Mr. W. Worby Beaumont, "Motor Traction in the Cold Storage and Ice Industries."

WEDNESDAY, DEC. 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Colonel Sir Charles M. Watson, "The Metric System."

Geological, Burlington-house, W., 8 p.m.

African, Criterion Restaurant, Piccadilly-circus, W., 8 p.m. Sir J. West Ridgway, "The Transvaal and Orange River Colony."

Entomological, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Mr. Philip M. Johnston, "Church Chests of the 13th Century in England."

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, DEC. 6..Antiquaries, Burlington-house, W., 8½ p.m.

Royal, Burlington-house, W., 4 p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Professor A. J. Ewart, "A Contribution to the Physiology of the Museum Beetle, *Anthrenus museorum* (Linn.)." 2. Mr. E. Burdon, "Note on the Origin of the name *Chermes* or *Kermes*." 3. Dr. A. T. Masterman, "An Abnormal Specimen of a Dab with three eyes." 4. Rev. H. Purefoy FitzGerald, "A Note on *Siegesbeckia orientalis* (Linn.)."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. J. S. Lumsden, "The Liquid Volume of a Dissolved Substance." 2. Mr. W. H. Perkin, junr., and R. Robinson, "Some Derivatives of Benzophenone. Synthesis of Substances Occurring in Coco-bark." (Preliminary Notice.) 3. Mr. J. L. Simonsen, "A Synthesis of Terebic, Terpenylic, and Homoterpenylic Acids."

London Institution, Finsbury-circus, E.C., 6 p.m. Professor Hans Wesseley, "Chamber Music."

United Service Institution, Whitehall, S.W., 3 p.m. Lieut. C. Bellairs, "The Standard of Naval Strength."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. R. J. P. Briggs, "Boilers and their Accessories."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Prof. J. Epstein's paper, "Selection and Testing of Materials for Construction of Electrical Machinery."

FRIDAY, DEC. 7...Geologists' Association, University College, W.C., 8 p.m. Dr. Arthur W. Rowe, "The Zones of the White Chalk of the English Coast (Part V.—Isle of Wight)."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Journal of the Society of Arts.

No. 2,820. VOL. LV.

FRIDAY, DECEMBER 7, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 10, 8 p.m. (Cantor Lecture.) A. D. HALL, M.A., "Artificial Fertilisers: their Nature and Functions." (Lecture IV.)

WEDNESDAY, DECEMBER 12, 8 p.m. (Ordinary Meeting.) CECIL H. HOOPER, "Fruit Growing and the Protection of Birds."

THURSDAY, DECEMBER 13, 4.30 p.m. (Indian Section.) A. YUSUF ALI, M.A., LL.M. (Cantab.), I.C.S., "The Indian Mohammedans: their Past, Present, and Future."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 3rd inst., Mr. A. D. HALL, Director of the Lawes Agricultural Trust, delivered the third lecture of his course on "Artificial Fertilisers: their Nature and Functions."

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION.

Tuesday afternoon, December 4th; the RIGHT HON. VISCOUNT MILNER, G.C.B., G.C.M.G., in the chair. The paper read was "The Cape to Cairo Railway," by SIR LEWIS MICHELL, late Member of the Cape Ministry.

The paper and discussion will be published in a future number of the *Journal.*

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, December 5th, 1906: Sir DAVID GILL, K.C.B., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Brookesmith, Frank, Dalrymple-road, Appleby, Invercargill, New Zealand.
Faulkner, P. Leo, A.S.P., Shillong, Assam, India.
Horsley, Gerald Calcott, F.R.I.B.A., 2, Gray's Inn-square, W.C.
Rouse, Herbert James, c/o. Messrs. Mackinnon, Mackenzie & Co., Ltd., Strand-road, Calcutta, India.
Wood, Thomas Alexander Stephen, Penshurst, Prince of Wales-road, Carshalton, Surrey.

The following candidates were ballotted for and duly elected members of the Society:—

Adams, Miss Katharine, Eadburgha Bindery, Broadway R.S.O., Worcestershire.
Addis, Frederick Henry, Assoc.M.Inst.C.E., B.B. and C.I. Railway, Mhow, Central India.
Akimoto, Viscount, 6 Kita Koga-cho, Surugadai, Tokyo, Japan.
Araki, Professor Kwampo, 3 Nishimachi, Shitaya, Tokyo, Japan.
Armstrong, Miss Carr, R.M.S., 76, Longridge-road-mansion, Earl's-court, S.W.
Asano, Sōichiro, 18, Kitashinbori-cho, Nihonbashi-ku, Tokyo, Japan.
Baillie, Mrs. A. H. Murray, 94, Eaton-place, S.W.
Baxter, Walter Stephen, 38, Mayflower-road, Clapham, S.W.
Beatson, E. B., Vicarsgrange, Eastbourne.
Bebianno, Domingos Alves, care of Mark Sutton, 130*a*, Rua Barão de Mesquita, Andarahy Grande, Rio de Janeiro, Brazil, South America.
Beech, Ernest William, 32, Lincoln-road, Peterborough.
Bisset, William Molteno, Colonial Mutual-buildings, Adderley-street, Cape Town, South Africa.
Blount, Lady E. A. M., F.R.S.L., 73, West-street, Brighton.

Bonner, Albert Edward, 18, Holland-street, Kensington, W.
Bonnor, John H. M., 10, Trafalgar Studios, Manresa-road, Chelsea, S.W.
Boright, Sherman H., Forbes Reef, Swazieland, South Africa.
Box, Eliab, 287-289, Broadway, Bexley-heath, Kent.
Brown, Miss Charlotte, 115, Gloucester-road, S.W.
Buck, James Henry Edward, A.M.I.Mech.E., P.O. Box 1,049, Johannesburg, Transvaal, South Africa.
Buckton, William Woodyer, B.A., 72, Victoria-street, S.W., and Royal Societies' Club, St. James's-street, S.W.
Bultitude, Henry Frank, 18, Philip-road, Peckham-rye, S.E.
Campbell, Richardson, Dunedin, Woodlands-street, Cheetham-hill, Manchester.
Carter, Major Evan E., C.M.G., M.V.O , Stanhope Lines, Aldershot.
Cartlidge, S. J., 9, Netherton-grove, Chelsea, S.W.
Chambers, James S., Kutais, Trans-Caucasus, and 5, Ionkovskafa, St. Petersburgh, Russia.
Chapin, Robert Williams, 28, Bishopsgate-street Within, E.C.
Choles, Major Frederick John, Ordnance Officer, Natal Militia, Pietermaritzburg, Natal, South Africa.
Chow, Taotai C. L., Imperial Railways of North China, Tientsin, China.
Clemens, Benjamin, 23, Fitzroy-square, W.
Collingwood, John James, Clovelly, Cecil-road, Upton Manor, E.
Cooper, J. Paul, The Elms, Castle Bromwich, Warwickshire.
Corkett, Frederic Thomas, 3, Redcliffe-gardens, Ilford, Essex.
Crocker, Ernest George, A.M.I.Mech.E., H.M. Naval Establishment, Rosyth, Fife, N.B.
Croll, James, Olaa Sugar Company, Limited, Olaa, Hawaii.
Cross, Reginald Thomas Green, A.M.I.Mech.E., Khoreel Tea Estate, Daloò P.O., Cachar, India.
Damania, Lieut.-Colonel P. J., Northbrook Society, 185, Piccadilly, W.
Davidson, Rev. William, The Manse, Chryston, by Glasgow.
Davies, James Bright, Northern Nigeria Enclave, Burutu, Southern Nigeria, West Africa.
Divecha, Ramchundra Nursey, A.M.I.Mech.E., Sugar-lane, Kaloopur Post, Ahmedabad, India.
Dixon, G. E., M.D., Heathfield, Chislehurst, Kent.
Dressler, Conrad, White-cottage, Marlow, Bucks.
Dyce, James S., Barberton, Transvaal, South Africa.
Eddy, Sidney Arthur, Carn Brea-house, Observatory, Cape Town, South Africa.
Emanuel, Frank L., 67, Ladbroke-grove, Kensington, W.
Etti, Captain Charles, M.A., The European Eastern Asia Trader Association, Limited, West India House, 98, Leadenhall-street, E.C.
Fisher, Henry Herbert, Calle Zapiola 2,075, Belgrano, Buenos Aires, Argentine Republic.

The paper read was–

SOME OBJECTIONS TO THE COMPULSORY INTRODUCTION OF THE METRIC SYSTEM.

By Colonel Sir C. M. Watson, K.C.M.G., C.B., R.E.

Certain persons are keen advocates of the metric system of weights and measures, and desire that a law should be enacted by Parliament to abolish British measures, and compel everyone in this country to use the French. At the present time both systems are legal in Great Britain, and everyone is free to make use of whichever suits him best. All that is insisted upon is that whoever uses the British measures must use the yard, pound, and gallon, as defined by the Act of 1878, and of which the standards are kept by the Board of Trade; while those who prefer to adopt the metre, the kilogramme, and the litre must, in this case also, use measures that are in accord with the legal standards kept by the Board of Trade.

This seems a reasonable arrangement, and one that should satisfy everybody, but it is not enough for the advocates of the metric system, who want not only to use the metric measures themselves, but to force others to do so also. As they push their views with great vigour, and as the majority of those who are content with the British measures care little about the question, one hears much of the arguments in favour of the metric system and very little of the arguments against it. It, therefore, seems desirable to state briefly, for the information of those who are interested in the subject, but have not had the opportunity of studying it, some of the reasons against the compulsory introduction of the metric measures.

The arguments usually brought forward in favour of the French measures may be summarised as follows:—

1. That the metric measures are thoroughly scientific, while the British measures are antiquated and unscientific.

2. That the metric measures are better suited both for ordinary and scientific use than the British, and that the decimal system of division is superior to the binary or to the duodecimal.

3. That the metric system has been fully adopted by most nations, and, therefore, its use would be very advantageous for British commerce.

With reference to the first of these arguments, it is necessary to give a brief *résumé* of the history of the metric system.

Prior to the French Revolution of 1792 the French measures were in an unsatisfactory condition. Although the Paris toise of six Paris feet, and the aune or ell of about 44 Paris inches were the legal measures of length, different measures were used in other parts of France. The measures of weight and capacity also varied from the legal Paris standards. From time to time, under the French kings, attempts had been made to introduce a uniform system of weights and measures, but without success.

In 1670, Gabriel Mouton, an ecclesiastic, of Lyons, proposed that the standard measure of length should be based on the length of a great circle of the earth; and, in 1671, Picard suggested that the length of a pendulum, beating seconds, should be adopted as the standard, the third part of this being made the universal foot. Nothing was done for more than a century, but, in 1790, a decree was passed by the French National Assembly, by which it was enacted that a system of measures was to be adopted, based on the length of the seconds pendulum. There was much to be said in favour of this. As the length of the seconds pendulum at Paris was 3·05936 Paris feet, the new universal French foot would have been

1·01978 Paris foot, so that the change from the existing legal standard would have been small. The question was referred to the Academy of Sciences for consideration. In the first report, dated October 27th, 1790, it was recommended that the decimal system of division should be adopted, and, in the second report, dated March 19th, 1791, it was proposed that the seconds pendulum should *not* be taken as the unit of length, because "it would depend on the adoption of an entirely arbitrary unit, *i.e.*, the second of time, and it would bring in questions of atmospheric pressure and the force of gravity, which have nothing to do with the unit of length." The Commission were of opinion that it was more natural to take a measure of the earth as a basis, and recommended the adoption of a quarter of a meridian, measured from the North Pole to the Equator, as the foundation of the new system. One ten millionth part of the quadrant was to be taken as the ordinary standard of length. This was arrived at by dividing the circle into 400° instead of 360°, the division which has been used from remote antiquity. Each of the new degrees was to be divided into 100 minutes, and each minute into 100 seconds. The tenth part of a second was to be the ordinary standard of length. This division of the circle into 400° is an essential part of the metric system, though it is conveniently overlooked by its advocates at the present time.

The Commission further recommended that an arc of the meridian from Dunkirk to Barcelona should be measured with the greatest accuracy, in order to ensure that the length of the metre, the standard of length, should be absolutely correct.

The report of the Academy was received by the National Assembly on March 26th, 1791, and on the 30th of March—four days afterwards—a decree was passed adopting the quadrant of the meridian as the base of the new system of measures, and ordering the immediate measurement of the arc from Dunkirk to Barcelona. On April 13th, 1791, commissions were appointed to carry out the necessary surveys and calculations. Such was the indecent haste with which the National Assembly adopted the project for upsetting all the existing weights and measures in France.

In the following year the great revolution took place. The monarchy was abolished, the National Convention took the place of the Legislative Assembly, and the Republic was proclaimed in September, 1792.

One of the great objects of the Republicans was to destroy the records of the past, and there can be no question but that this was one of the main reasons for the adoption of the metric system. They were so anxious to do away with the old measures at once that they could not wait until the arc of the meridian had been surveyed, and the true length of the metre ascertained, but fixed it provisionally as equal to 36 Paris inches and 11·442 lines, *i.e.*, 3·07946 Paris feet.

On August 1st, 1793, a decree was passed by the National Convention, in which it was enacted that the new system of weights and measures was to be the only one to be used in the Republic. The time when this was to become obligatory was fixed at one year from the date of publication of the decree. The names of the new measures were quite different in many respects to those afterwards adopted. For example, the kilometre was called "millaire," the litre, "pinte," and the kilogramme, "grave."

This decree was followed by others. The Christian era was abolished, and replaced by the Republican calendar, the first day of which was September 22nd, 1792. The months were altered; the week was divided into ten days, and the day into ten hours, so as to be in accord with the decimal system. The circle was divided into 400° instead of 360°, in accordance with the arrangement I have already referred to. Unfortunately the heavenly bodies continued to move as before, which caused a blot on the system, as the year should have been 400 days, and the lunar month forty days. Under the actual circumstances the Republicans had to be content with twelve months in the year, and three weeks in the month.

As the circle was divided into 400°, the division of the day into 10 hours was essential. In the operation of astronomy and navigation, it is constantly necessary to convert time into arc and *vice versâ*. With the circle divided into 360°, and the day into 24 hours, an hour of time is equivalent to 15° of arc; with the circle divided into 400° and the day into 10 hours, an hour is equivalent to 40° of arc; but with the circle divided into 400° and the day into 24 hours, the hour and degree have no simple relation to one another. Even the Republican Government were not strong enough to force the ten-hour day on France, and it only lasted a year and a half. The division of the circle into 400° has practically never been adopted, and French navigators still use the circle of 360° and the geographical

mile of one-sixtieth of a degree, instead of the kilometre, which was to be the geographical mile of the new scientific system. The metric system has therefore failed to meet the requirements of navigation.

The Republican calendar and the week of 10 days lasted a little longer than the day of 10 hours, but these also were abolished by a decree issued in 1805, and the attempt to apply the decimal system to the division of time came to an end.

That the main object of the adoption of the metric system in France was not so much the introduction of a scientific system as the obliteration of the records of the past, is abundantly clear from various reports upon the subject.

For example, in an address presented to the National Convention by the Commission of Weights and Measures on January 19th, 1794, the following paragraph appears:—

"To obtain this latter result (*i.e.*, the exact determination of the length of a quadrant of the meridian) the members of the Commission are engaged in measuring the length of an arc of the meridian between Barcelona and Dune-Libre.* But while they are completing the measure, and fixing, with an accuracy hitherto unknown to the nations of the world, the exact unit which will be embodied in the standards that are to serve as types and to be kept by the National Convention, we have considered it indispensable to find immediate means of distributing the new weights and measures to the whole Republic. Soon this benefit will be extended to all citizens. Soon their eyes will no longer be shocked by those ancient weights and measures which still call to mind the odious remembrance of times and things soiled by tyrants. Republican weights and measures must necessarily take the place of the ancient ones."

Again, in a report to the Convention by C. A. Prieur, on March 1st, 1795, we find the following remarks;—

"The unity of the Republic demands that there shall be unity in weights, as there is unity in money, unity in language, unity in legislation, unity in government, and unity of interest to defend ourselves against the attack of our enemies, and advance toward all kinds of prosperity. How can the friends of equality endure an inconvenient system of measures which keep up the memory of the shameful feudal slavery? Is it not a contradiction for republicans to measure their fields by the royal arpent, or to use a royal toise or a royal foot, when they have sworn to execrate every denomination of tyranny, whatever it may be."

On the receipt of this report by the National Convention a decree was passed on April 7th, 1795, enumerating the new standards. These were as follows:—

1. The "metre," the standard of length, equal to one ten-millionth part of a quadrant of the meridian, between the North Pole and Equator.

2. The "are," the standard of surface, equal to a square of ten metres side.

3. The "stère," the standard of volume, equal to a cubic metre.

4. The "litre," the standard of capacity, equal to the cube of the tenth part of a metre.

5. The "gramme," the standard of weight, equal to the weight of a volume of pure water at the temperature of melting ice, contained in a cube of the hundredth part of a metre.

The decree ordered the new standards to be prepared as quickly as possible and distributed throughout the country. But four years more elapsed before the scientific men who were engaged on the work of measuring the arc of the meridian had completed their labours. The manner in which the operations were conducted is worthy of the highest praise, and, owing to the disturbed state of France, the difficulties were very great. Delambre, who had charge of the northern portion of the arc, extending from Dunkirk to Rodez, was constantly opposed by the people, notwithstanding the passports given him by the National Convention, and Mechain, who measured the southern part of the arc, from Rodez to Barcelona, also met with opposition, and had the misfortune to be incapacitated for a time by a serious accident, from which he never completely recovered.

It was not until April 30th, 1799, that the geodetical operations were completed, the calculations made, and the final Report prepared. The result was, that the length of the quadrant of the meridian was calculated as equal to 5,130,740 Paris toises, of which the $\frac{1}{10000000}$th part was of 36 Paris inches and 11·296 lines, equal to 3·0785 Paris feet. On May 30th, 1799, the Commission appointed to fix the kilogramme reported that a cubic decimetre of pure water at maximum density weighed 18,827·15 French grains. Platinum standard measures of the metre and kilogramme were made in accordance with these determinations, presented to the Legislative Assembly, and finally deposited in the Archives on June 22nd, 1799. These standards remain the standards of French measures to the present day.

Unfortunately, notwithstanding the care taken by Delambre and Mechain, their results

* The name of Dunkirk appears to have been changed to Dune-Libre to suit republican ideas.

were not absolutely correct, and, in consequence, the metre, as determined by them, is a little less than the $\frac{1}{10000000}$th part of a quadrant of the meridian. Colonel A. B. Clarke, C.B., in his work entitled "Geodesy," has give the length of the true metre as equal to 39·37779 British inches.

The following is a comparison of the values:—

	British Inches.
Provisional metre of 1793	39·382134
Definitive metre of 1799	39·370113
True metre (Clarke)	39·377790

On December 10th, 1799, a decree was passed abolishing the provisional metre, and fixing the length of the metre and weight of the kilogramme in accordance with the standards deposited in the Archives. Steps were then taken to make copies of the standards and distribute them throughout France.

When the International Commission on the metre met in Paris, in 1870, it was decided not to attempt to construct a metre more theoretically correct, but to take as the basis the standard metre constructed in 1799. The same course was taken with regard to the kilogramme. Careful investigation showed that the weight of the standard kilogramme of 1799 was slightly greater than that of a cubic decimetre of pure water at its maximum density; but, having regard to the difficulty that would be caused by a change in the weight of the kilogramme, it was decided to adhere to the standard of 1799, and to make the litre of such a capacity as to contain a volume of pure water exactly equal in weight to the standard kilogramme. This was an important decision, as it made the litre depend on the standard of weight, instead of the litre and kilogramme depending, as originally proposed, on the standard of length.

The following is a *résumé* of the metric system as originally designed and as it actually exists:—

Original Metric System.	*Actual Metric System.*
1. The circle to be divided into 400°; each degree into 100′; each minute into 100″.	1. The ancient division of the circle into 360° remains; each degree being divided into 60′, and each minnte into 60″.
2. The Metre, the standard of length, was to be exactly $\frac{1}{10000000}$th of a quadrant of the earth's surface, measured from the North Pole to the Equator—*i.e.*, 1-10th of a new second of arc.	2. The Standard Metre is slightly less than $\frac{1}{10000000}$th of the quadrant, and is, therefore, an arbitrary measure.
3. The Litre, the standard of capacity, was to be exactly equal to the cube of the tenth part of the Metre.	3. The actual Litre is the volume occupied by the quantity of pure water which weighs exactly 1,000 Grammes. It is slightly larger than a cubic decimètre.
4. The Gramme, the standard of weight, was to be exactly equal to the weight of a volume of pure water, contained in the cube of the hundredth part of the Metre. The kilogramme, or 1,000 grammes, was consequently to be the weight of the volume of pure water contained in the litre.	4. The Kilogramme, the actual standard of weight, is a platinum weight which was deposited in the Archives in 1799. It is slightly larger than the theoretical kilogramme, and is consequently an arbitrary measure. The actual gramme is the thousandth part of a kilogramme.
5. The Are, or standard of surface, was to be the square of ten metres.	5. As the actual Metre is slightly shorter than the true Metre, so the Are is slightly smaller than the true theoretical Are.

It will be seen from the above that all the metric measures differ from their true theoretical values, and depend upon two arbitrary measures, the standard metre and the standard kilogramme, exactly in the same way as the British measures depend upon two arbitrary measures, the standard yard and the standard pound. It is clear, therefore, that the metric standards cannot be regarded as perfectly scientific, or, as superior, in this respect, to the British standards.

When these facts are pointed out to an advocate for the compulsory introduction of the metric system into England, the usual reply is, that, at all events, the standards are nearly what they profess to be, and that, in any case, the measures in themselves are better than the British, and that the decimal system of division is very superior to the binary or duodecimal. These points deserve careful consideration. The British measures are founded on natural units, and have descended to us from a remote antiquity. The yard is the direct representative of what was probably the oldest measure in the world, *i.e.*, the cubit, which is the length of the forearm of a man of average stature, measured from the elbow to the top of the middle finger. A yard is two cubits. It is rather remarkable, that, while in the case of the yard, the derivation from the cubit is almost forgotten, the Indian "gaz," which is equal to the yard, is still divided into two "haths" or cubits. The foot is also a very ancient measure,

and though it varied considerably in different countries, it was usually about two-thirds of a cubit. The British yard is divided into three feet, or thirty-six inches. This number is divisible by 2, 3, 4, 6, 9, 12, and 18. The metre on the contrary is divided into ten decimetres, each decimetre into ten centimetres, the latter being the nearest unit to the inch. There is no division of the metre corresponding to the foot. The decimetre is too small to take the place of the foot as a unit, and it is little used. The absence of a unit of about the length of a foot is a blot on the metric system. Similarly, the inch is a better unit for ordinary purposes than the centimetre, which is too short, about four-tenths of an inch. The $\frac{1}{100}$th inch is better than the millimetre, as it is the smallest measure that can be seen conveniently with the naked eye, while the millimetre is too long.

As regards the decimal system of division, this is not a monopoly of French measures, and the British measures can be so divided by anyone who chooses to do so. But whereas in the French system, the decimal division only can be employed, in the British other fractional divisions are also applicable. For example, a carpenter prefers to use the inch divided into eighths and sixteenths, whereas for scientific and other accurate measurements, it is better to divide the inch into tenths, hundredths, and thousandths.

The pound is also an ancient measure, which has been used by many nations. It is certainly more convenient as a unit than the kilogramme, which is too heavy. Similarly the gramme is too heavy for ordinary purposes, and is not so good a unit as the British grain. But, on the other hand, the gramme is too small as the primary unit of weight, and its place as such in the metric system has been taken by the kilogramme. For use in ordinary life, the binary system of dividing weights has great advantages, although, for scientific purposes, there is a great deal to be said in favour of the decimal division. It is sometimes overlooked that scientific weighing and measuring is different to the weighing and measuring of every-day business. In the former, the object is usually to ascertain the size or weight of a given thing, whereas in the case of the latter, the object is to make a thing of a given size or weight. For this, the division by halves, quarters, &c., is more convenient than the decimal system.

For money, on the other hand, the decimal system has considerable advantages, because, in questions dealing with money, there is a great deal of addition to be done. If the advocates of the metric system would devote their energies to the introduction of a decimal system of coinage into this country there would be something to say in favour of it. At the same time, I doubt whether the Englishman would ever be willing either to give up either the penny or the pound, and it is evident that one or other must be sacrificed before a decimal system of coinage could be introduced.

As regards measures of capacity, I have already pointed out that, from a scientific point of view, there is nothing to choose between the British and the metric systems, as the gallon and litre, the standards of capacity, are both dependent upon the units of weight. The gallon is the volume occupied by ten pounds of pure water, while the litre is the volume occupied by one thousand grammes of pure water. But for measures of capacity, the multiplication or division by 8 (2^3) is better than the multiplication or division by 10. It is not generally realised how the British measures of capacity are related to the unit of length, but it is worth pointing out that a bushel (eight gallons) is a cylindrical measure very nearly half a yard in diameter and a quarter of a yard in depth, the gallon a similar measure, a quarter of a yard in diameter and one-eighth of a yard in depth, and so on. But in the metric system the multiples and subdivisions of measures of capacity have no convenient relation to one another as regards lineal measure.

There is one very important industry for which, judging from the practical experience of many nations, the metric system is not well adapted. I allude to the textile industries. In this case, even in France, after more than a hundred years, the metric standards have not completely replaced the old measures, notwithstanding the great efforts that have been made to force the manufacturers to give up the measures that they were accustomed to and adopt the new system. In the silk business, for example, the skeins are still based for length on the aune, and for weight on the denier. Decrees have been enacted in France from time to time ordering the application of the metric system to the textile industries, and, notwithstanding these, the present condition of affairs has been described in a recent publication ("L'Industrie Textile") by Monsieur Lamoitier, who says: "We (*i.e.*, the French) are as much in the anarchy of weights

and measures in the textile industries as at the time of the Revolution."

It is remarkable how entirely the question of the difficulty of using the metric system in textile manufactories was avoided by the House of Lords Committee who considered the Metric Measures Bill in 1904. In his evidence before this Committee Sir H. Jekyll, Assistant Secretary of the Board of Trade, said: "It is believed that the English yard is the measure by which silk and cotton are manufactured even in metric countries. It may be advisable to retain the yard as a measure for these trades." But, notwithstanding this very important statement, no evidence on the subject appears to have been called for, and no one interested in textile manufactures appears to have been examined. This was a serious omission, as these industries are a most important branch of British manufactures, and if the metric system is unsuitable for them it is a strong argument against the compulsory use of it in this country. The question of the difficulty of applying the metric system to textile manufactures is discussed fully in a paper read by Mr. F. A. Halsey before the American Society of Mechanical Engineers, New York, in December, 1902. There is also a useful paper on the subject by Mr. S. Dale, which is included in Mr. Halsey's work, "The Metric Fallacy," published at New York in 1904. These two papers should be carefully studied by those who wish to understand the question of the metric system as applied to textile industries.

There is another kind of measurement respecting which it would be extremely difficult in Great Britain to replace the British measures by the metric. This is the measurement of land. In his evidence before the House of Lords Committee, in 1904, Colonel Johnston, C.B., the Director General of the Ordnance Survey, pointed out the grave inconvenience that would be caused by the use of the metric system for land measurements, and the Committee inserted a clause in the Bill to the effect that the metric measures should not be applied to the linear or superficial measurement of land. It is not easy to understand how this was intended to work. Could it have been meant that the length of a road was to be measured by the metre, while the land alongside the road was to be measured by the yard? But if, on the other hand, the measurement of roads was to be regarded as a land measurement, it would not be logical to measure the length of railways by the kilometre. In any case it would mean having two compulsory systems of linear measurement, which would not be advisable.

As regards nomenclature, the British system has great advantages over the French. The words "mile," "chain," "yard," "foot," and "inch" are more distinctive and less likely to lead to confusion than "kilometre," "metre," "decimetre," and "centimetre." Similarly, "pint," "gallon," and "bushel" are more distinctive names than "decilitre," "litre," and "decalitre."

On the whole, it seems to me that the British measures are more convenient standards for use in ordinary life than the metric measures, while the fact that they can be used with the binary and duodecimal system of multiplication and division as well as the decimal, makes them more elastic and suitable for different purposes than the metric, to which the decimal system of division alone is applicable.

I now come to the main argument which is used by the advocates of the compulsory use of the metric system. It is well stated in a pamphlet which has recently been issued by the Decimal Association, a society which devotes much energy to making metric measures compulsory in the British Empire. In this pamphlet we find the following statement:—

"The chief reason of all is that we now make difficulties for ourselves in relation to our foreign trade with metric countries, and lose business because we do not manufacture and sell in terms of the metric system. To avoid the trouble, confusion, and expense of having one system of weights and measures for our home trade and another for our foreign trade, we should adopt the metric weights and measures for all purposes, and so place ourselves on an equal footing with our competitors.

"Our customers in the metric countries, which have a population of over 483,000,000, do not understand quotations and specifications based on British weights and measures. Often they cannot spare the time required to calculate the metric equivalents, and prefer to deal with Germans and other makers who use the metric system."

The implication made in these statements is that as metric measures are more largely used than the British measures, therefore it is the duty of Great Britain to give up her own measures and adopt the French.

But this argument is based on a fallacy, because at the present time there are a larger number of people in the world who use measures based on the British yard or foot than of those who use the metre, so that if there is any question of one measure giving way to the other, it is the metre that should give way to

the yard. The statement quoted above implies that the number of people who use the mètre is 483,000,000, but no proof is given of this, and an examination of the population of the different countries does not justify it.

In the following Table I have enumerated roughly the population of the different countries of the world, classified according to the measures commonly used :—

I.—*Countries in which the Yard is the Standard.*

	Population.
Great Britain and Dependencies	398,000,000
United States and Dependencies	91,000,000
	489,000,000

II.—*Countries in which the Metre is the Standard.*

	Population.
France and Dependencies	96,000,000
Germany and Dependencies	70,000,000
Austria-Hungary	45,500,000
Holland and Dependencies	41,500,000
Italy and Dependencies	32,500,000
Portugal and Dependencies	14,600,000
Belgium	7,000,000
Roumania	6,000,000
Sweden	5,000,000
Switzerland	3,300,000
Norway	3,000,000
Servia	2,500,000
	326,900,000

III.—*Countries which use Native Measures, in which the Metre is used to a certain extent.*

	Population.
States of South America	36,500,000
States of Central America	23,600,000
Spain	18,600,000
Denmark	2,500,000
Greece	2,400,000
Cuba	1,600,000
	85,200,000

IV.—*The Larger Countries which use their own Native Measures.*

	Population.
China	426,000,000
Russia	130,000,000
Japan	46,700,000
Turkey	24,000,000
Egypt	9,700,000
Morocco	9,400,000
Persia	7,600,000
Afghanistan	5,000,000
Abyssinia	4,000,000
	662,400,000

It will be seen that the total population of the countries which use measures based on the British yard are greater in number than those who use the metre, even assuming that all the people in the countries classified under the metre really used it. But this is far from being the case, as there is probably not one of these countries, where the old measures are not used to some extent. I have already shown that this is the case in France, where the metric system was invented, and where it has been longest in use. On the other hand, in some countries where British measures are not supposed to be used, they are actually employed to some extent. Mexico is an instance of this. In consequence of its proximity to the United States, it is natural that the United States' measures are considerably used, and these of course are the same as the British measures.

Even in the countries which use their own measures, as given in Table IV., in several cases the standards of length are approximate to the British. In Russia, for example, the imperial foot is the same as the British, and in China the *chih* and in Japan the *shaku* are almost identical with the British foot.

Without discussing whether the argument based on numbers has much weight, it is at all events reasonable to say that any such argument will be in favour of the yard, the foot, and the inch, rather than the metre, and to assert that we make difficulties for ourselves because we prefer to adhere to our own measures is unjustifiable.

As regards the argument that it is important that all nations should have the same weights and measures, it may also be said that it would be convenient if they all spoke the same language and used the same system of money. All scientific persons must know French and German, and all British merchants should know the language of the country with which they do business. But this would not be a reason for compelling the British people to give up their own language, and learn another. And it would be equally unreasonable to give great trouble as regards measures to many millions of people for the convenience of some scientific persons and of British merchants engaged in foreign trade with some countries.

It is doubtful whether the compulsory introduction of the metric system into this country would have much effect on increasing British trade. At all events it is fairly certain that such a change would be more in favour of the foreigner than of the Englishman, as it would

simplify the matter of exports to Great Britain from metric countries. But at present the French and German producers do not seem to have any difficulty in making articles for export to Great Britain, notwithstanding the difference in the system of weights and measures, nor do they appear to refuse British goods because we have not adopted the metric system.

There is, however, one matter in which British manufacturers and merchants might effect an improvement without inconveniencing anyone, and that is by printing their catalogues and trade circulars in the language of the country with which they are dealing, instead of in English. I have noticed, when travelling abroad, that while German trade catalogues are usually in the foreign language, this is frequently not the case with English catalogues. It is probable that a change in this respect would produce more effect than the compulsory introduction of the metric system into Great Britain.

It is difficult to say what proportion the advocates of the compulsory use of the metric system in this country bear to the whole population, but they are certainly a small minority. The greater part of the people appear to be satisfied with the existing measures, and have no wish for a change. It is the same in the United States, where I recently lived for some time, and took some trouble to ascertain the views of the people on the subject. There also the metric system is permissive, but the large majority continue to use the British yard and pound, and show no wish for a change, notwithstanding the zeal with which the missionaries of the metric measures preach their crusade. A few years ago, a Bill was introduced into Congress for the compulsory use of the metre, but it had to be dropped, and any future Bill will probably meet the same fate. The probability of the abolition of the existing standards in the United States is very small, and this, of course, is a strong argument against their abolition in this country, as our trade with the United States is greater than with any other foreign country. To change the measures of any nation is a matter of great difficulty, but to change the measures of the Anglo-Saxon race would probably be impossible.

As I have already pointed out, there is perfect freedom in this country for anyone who wishes to use the metric system. Why should the same freedom be denied to the great majority who are quite content with the British system? I cannot but agree with Napoleon, who is reported to have said on this subject, "It is a tormenting of the people for mere trifles."

DISCUSSION.

The CHAIRMAN stated that Lord Kelvin, who was unable to attend the meeting, owing to the state of his health, had sent him the following letter, with the request that he would read it to the meeting:—

Dear Sir David,—I am sorry I cannot be present on Wednesday evening to hear Colonel Sir Charles Watson's paper on the Metric System, of which I have read an advance printed proof with much interest, though I do not consider valid any of his objections to its compulsory use in the United Kingdom, and India and the British Colonies. I am sure his historical sketch of its origin in France will greatly interest all present at the meeting. There is one important detail in which I thoroughly agree with Sir Charles Watson—the centesimal division of the quadrant was an unwise and unfortunate proposal, which was never practically adopted. It has somewhat marred the otherwise thoroughly practical system for measurement of length which distinguished French men of science have given to the world. If they had thought of the enormous inconvenience of calling the angle of an equilateral triangle 66 degrees and two-thirds, instead of 60 degrees, as they had it of old; and if they had continued, as of old, to divide the degree into 60 minutes, we should now have our present nautical mile, and its thousandth part, the fathom, as the foundation of our whole metric system. Our nautical mile is too convenient for use at sea, and for all geographical measurements on land, to allow it to be abandoned. It remains with us, and is a monument of the one blemish on the French metric system, in all other respects so admirably useful and convenient for all measurements of length, area, volume, and weight. Sir Charles Watson tells us that "in 1670, Gabriel Mouton, an ecclesiastic of Lyons, proposed that the standard measure of length should be based on the length of a great circle of the earth." That was a very practical proposal, remarkably in contrast with suggestions made in England about 150 years later that we might found measurements of length on a diameter of the earth. We do not travel in a line through the earth's centre when we make a journey to the Antipodes; we do make all our journeys on the earths's surface, and it is very convenient to know that a quarter round the earth is ten thousand kilometres.

The fact, noticed by Sir Charles Watson as having been discovered by Colonel Clarke in his grand Geodetic work, that the metre ought to be about 1-5000th longer to fit the original French definition is interesting, but is of no practical importance. The true metre is now the length of the standard metre

constructed in Paris in 1799, and adopted by the International Commission of 1870. Many copies, thirty I believe, were made in platinum, and multitudinous verifications of their agreement with one another were made with all possible care. Two of these copies we have in England; and virtually the whole world is now supplied with exceedingly accurate copies of the standard metre; accurate enough for all practical and scientific purposes.

If every one of the existing standard metres, by some almost infinitely improbable concurrence of accidents, were destroyed, we can, for a continuance of accurate measurements in accordance with the present metric standard, fall back on the wave-length in vacuum of either of the chief constituents of sodium light, according to a brilliant idea suggested by Clerk Maxwell, about thirty years ago, and made thoroughly practical, within the last ten or fifteen years, by Michelson, in the splendid optical methods which he worked out finally in the Paris Bureau at Meudon, of the International Commission, for standards of practical and scientific measurement.—Yours truly,

(Signed) KELVIN.

The CHAIRMAN, in opening the discussion, thought the author had spent a good deal of excellent argument, and some sarcasm, in knocking to pieces a metric system which was originally set up in a hurried and imperfect manner by people only anxious to revolutionise everything. The metric system of that day was not the metric system of the scientific world of the present day. The present system had its headquarters in the International Bureau of Weights and Measures at Sevres, and was by far the most complete and scientifically accurate that existed. For example, the original platinum metre had been separately compared with each of the thirty existing copies, and they in turn had been separately inter-compared, so that the most accurate possible inter-comparison of those metres had been obtained. There was not the least doubt that, at the present moment, those metres were known to an accuracy of something like one five-millionth part of their length, an accuracy which was amply sufficient for the most extreme demands of science and supremely above all the possible requirements of ordinary practice. The author had objected to the fact that the kilogramme was not based rigorously upon the metre. It was very closely so, and would ultimately be made absolutely so rigorous by the refined methods of the International Bureau, thus nothing need be said upon the point. He desired at once to brush aside all arguments upon the acceptance or non-acceptance of a perfect method, because the international machinery already existed for a perfect system from a scientific point of view. Objections were made to the introduction of the metric system because the manufacturers of textile fabrics and the like had not adopted the system, although by law it was the only legal system in France. He was not at all sure that, if the metric system was compulsory in England, manufacturers would be obliged to employ, in the technical arts for the details of construction, threads and screws which were an exact part of a millimetre or an exact number of millimetres. They would not be required to put so many threads into the millimetre of a textile structure, but they would be compelled to sell their product by the metre. He was perfectly prepared to admit that the unfortunate fact that a man had ten fingers, including his thumbs, and this had practically compelled the world to adopt the present system of arithmetic, and that if the advice of Charles XII. had been followed and duodecimal arithmetics had been adopted, they would have had the perfection of a duodecimal system of measurement. It was now perfectly impossible to introduce duodecimal arithmetic; it was a dream of the future: and in the meantime, for the conveniences of life, they had to adopt the present system of arithmetic, and, he maintained also, the decimal system which was contained in metric measurement. He believed every country which had adopted it for sales and bargains on large scales had found it most convenient, and had certainly not given it up. The author had given the number of people in various countries who used the different systems, and had boldly put down Great Britain and its dependencies, with a population of 398 millions, as using the yard as the standard. He thought it would have been much fairer if Sir Charles had only given the figures for the intelligent white people of the Empire, who were capable of forming an opinion about standards, and, if he had done so, the people using the yard as the standard would appear in a very large minority. It must also be remembered that, whether they were in a majority or minority, they had had hundreds of years of use in which to obtain their advantage, whereas those who advocated the metre had had only a comparatively short time at their disposal in which to press their views.

Lord BELHAVEN AND STENTON stated that in 1904 he introduced a Bill in Parliament for the compulsory adoption of the metric system in four years' time, which would have given the people of the country plenty of time in which to become thoroughly acquainted with it. The Chairman was perfectly correct in saying that compulsion would go no further than insisting that the metric system should be adopted for the purchase and sale of articles which could be measured and weighed for ordinary trade, and would not interfere with screws or textile fabrics being made on any old system the manufacturers liked. The first part of the paper was taken up with an interesting review of the history of the metric system, but for all practical purposes the question was purely academic if not antiquarian. He must take objection to the author's statement that the division of the circle into 400 degrees was an essential part of the metric system, because it formed no part of the metric system which they desired to

introduce. The Chairman had so ably replied to the author's criticism with regard to the accuracy of the metre that he would not refer to that subject except to mention that it might not be generally known, as it was not known when the measurements were made from Dunkirk to Barcelona, that the earth was not a regular sphere nor even a regular oblate spheroid and owing to irregularities of land and water the distance from pole to the equator varied. He was told on very reliable authority that there was a certain meridian in the eastern portion of Asia where the distance from pole to equator would measure exactly ten million metres. That he thought quite disposed of any objection to the metre not being exactly correct, for if the meridians varied, and the metre conformed, there would be a different metre in every part of the world. Passing on to a more practical question, he would like to ask why they should cling to a yard because it was equal to two ancient cubits which must certainly have varied in countries inhabited by the tall inhabitants of Northern Europe or those of the much smaller Southern nations, to say nothing of the difference of length of the forearm in different individuals. After the extreme accuracy for which Colonel Watson had just been advocating, he thought the old cubit was rather a "come down." He could not but think that the author's views of convenience were considerably biassed by habit and custom, and a disinclination to think in any other measures than those he had always employed, and that the idea that a metre was too long and a centimetre too short for convenience would appear a most extraordinary one to a Frenchman or German who never used anything else. Similarly, Sir Charles said, an English carpenter preferred the inch divided into 8ths or 16ths, but he should be very much surprised if a German carpenter would like such measures. When the author said that 100th of an inch was better than a millimetre because it was the smallest division that could be seen by the naked eye he admitted it was a reasonable hypothesis although he did not exactly agree with him. The fact was that a millimetre, which was about 1-25th of an inch, was a larger division than that which could be clearly seen, while 100th of an inch was too small, divisions of 1-50th being as small as most people's eyes could easily mark. But in that connection everything turned upon the particular trade or business in which the scale was employed. In connection with the subject of decimal coinage to which the author had referred, the advocates of the introduction of metric weights and measures were all in favour of the decimalisation of money, but those favouring the reform were divided into two camps, the one favouring the pound as a basis and the other the penny. For the present, therefore, the question which did not affect the other was shelved; at any rate it did not affect English trade and commerce in nearly the same degree as the similarity of the weights and measures used by different countries. With regard to the tables of population given of countries using and those not using the metric system, the author had added to the latter the whole population of India. The millions of natives had their own weights and measures which had come down to them from ancient times, and on the other hand Sir Charles had omitted Japan and the South American Republics which had adopted the metric system. The author had asserted that the metric system was not well adapted to textile industries. That was an entire misconception, and if anybody was in doubt on the subject he recommended them to read a pamphlet by M. D. Chedville. In France, the system was simplicity itself. The metric system was particularly suitable to the textile industry, because by the use of a far less number of figures than were used in the English system, it was possible to find the length of yarn required, or the weight of material, in fact it was so simple that it hardly required any calculation at all. The same counts of yarn were not used all over England, different counties having different systems, for instance, three different systems prevailing in Yorkshire, Aberdeen, and Halifax. An International Congress was held in Paris, in 1900, on the unification of the counts of yarn, and it was there decided that the metric system should be adopted, but England could not take advantage of the decision so long as its antiquated weights and measures were retained. The author had also raised the question of the measurement of land. A great expense would be incurred in completing all the ordnance surveys of 1 inch or 6 inches to the mile, to a metrical division of 1 by 50,000, but that was the only objection. Some time ago the Ordnance Survey commenced a decimal system, because the whole of the towns were now surveyed, printed, and mapped out on a scale of 1 in 500, whilst the whole of Great Britain had long since been mapped out on a scale of 1 in 2,500. It was therefore only necessary to put the metre scale upon that and read the number of metres upon it with an ordinary metre scale used by a Frenchman or a German. If the map were reduced by photography to 1 in 50,000 the map of England would be of the same scale as that of France, Germany, and Switzerland. He did not think the author could have seen the consuls' reports which were sent home to this country year after year saying that trade was being lost by the manufacturers of this country because when people abroad desired to purchase an article they could not understand English weights and measures. One or two points were entirely left out of the paper, particularly the education of the child. One point which they claimed as an advantage for the metric system was that a child should not have to spend one, two, or even three years in learning tables which he forgot immediately afterwards, but that a simple system of weights and measures should be adopted so that he would no longer have to learn compound multiplication, compound division, compound addition, and that terrible thing called practice.

All those things would disappear, and the work of taking out the prices of any quantity of things in length and weight would be done in a moment without any compound rules. Another important consideration was the question of calculations in ordinary life. The engineer felt the disadvantage most, because he was troubled with having to deal with such awkward figures as $30\frac{1}{4}$ square yards in a pole, and many other difficulties, whereas a cubic centimetre of water weighed 1 gramme, a cubic decimetre of water weighed 1 kilogramme, and a cubic metre of water weighed one metric ton, and given the specific gravity of any substance it was only necessary to multiply the capacity by the specific gravity to obtain the weight. When he introduced his Bill in 1904 he presented an enormous number of petitions, and when he moved the third reading he summed them up as follows:—"The town, city, and county councils which presented petitions represent a population of eight millions; 50 chambers of commerce have petitioned, as well as 42 trades unions, representing 300,000 members; 60 teachers' associations, inspectors of weights and measures in 80 districts, and 30 retail trades associations." Finally, it might be of interest if he stated that they were promised the support of 400 members of the House of Commons in the present Parliament whenever a Bill was introduced.

Mr. THOMAS PARKER stated that at one time he had the metric craze and advocated the use of the metric system, but after carefully studying the subject he discovered it was a delusion and a mistake. It was absolutely untrue to say that British measures could not be scientifically used. The inch, the square inch, and the cubic inch had been in use practically for all time, the only difficulty that had arisen being that there was no unit of weight based upon the linear measure of the inch. If a cubic inch of water was adopted as the unit of weight, a much better measure would be obtained than the metre.

Mr. ALEXANDER SIEMENS stated that the commencement of the author's paper reminded him of the old story of the solicitor, who, in instructing counsel, said there was no case, and, therefore, he was to abuse the plaintiff's attorney. Sir Charles absolutely ignored the fact which he (Mr. Siemens) brought forward some years ago, that the metrical system really originated with James Watt, who said that any rational person would see that the decimal division was the proper thing to adopt. Professor Smith, of Birmingham, put it in a different way when he said that the system of weights and measures ought to be systematised on one basis of ratios throughout. That embodied the great advantage of the metric system. The second condition was that the basis ratio must be 10, because all arithmetic was based on 10. A great deal had been heard of the good old English weights and measures, but in his opinion that was a fallacy. Up to 1824 the pound avoirdupois, which had been used since time immemorial, was not legal. It was casually mentioned in the Weights and Measures Acts of 1760 that it was 7,008 grains, but in 1824 that was altered to 7,000 grains, while the Act contained in its preamble words to the effect that, owing to the chaotic state in which the weights and measures of Great Britain were, some imperial measures must now be created. Even the Act of 1824 did not accomplish everything, because it allowed heap measures in bushels, and the present system was really introduced in 1834. It was not the fact, as had been stated, that the United States were using exactly the same measures as England, and they ought therefore not to be ranged together. The Parliamentary Committee appointed in 1861, stated in their Report that it was no use to try to introduce a purely British system, because in a few years the country would be compelled to adopt an international system, and two changes would then be made instead of one. Even if he were prepared to say (which he was not) that the inch was better than the centimetre, it was impossible now-a-days. The German Customs Union appointed a committee in 1861 with orders to invent a national German system, but soon after commencing their labours they reported that it was an impossible task, because it was certain that with all the means of inter-communication between various countries, an international system must be adopted. In that respect only two systems could be considered, the English system and the French system, the latter of which had a systematised base ratio of 10 all through, while the former had all sorts of ratios. A good deal had been said about the duodecimal system, but the division was not duodecimal. For instance, he would like to know how many ounces there were in the third of a pound. The question of the compulsory introduction of the metric system reminded him of a very shrewd remark made by an Inspector of Weights and Measures, who was against compulsion because if shopkeepers had two sets of weights and measures on the counter they would know perfectly well what would happen to the unwary customer. The great stalking-horse trotted out against the metric system was the textile industry. He remembered that, when giving evidence before the Select Committee on Weights and Measures in 1895, he was asked the following question by Mr. Whiteley:—"Taking the cotton trade, a standard make is what is called 79 inch $37\frac{1}{2}$ yards $8\frac{1}{4}$ lbs. shirting, which is known all over the world wherever that shirting goes at the present time. It is known as of certain weight, length, and width; would it not in some way damage the reputation of that shirting if those figures had to be re-calculated in all the markets of the world?" He was sorry to say he was taken aback at the time, and made an answer which was not worth reproducing. But subsequently he turned the figures into metric measures, and found that the 79 inches were 2·066 metres, the $37\frac{1}{2}$ yards were 34·3 metres, and the $8\frac{1}{4}$ lbs were 3·75 kilogrammes;

so that the textile industry were practically using metric measures only they did not call them so.

Mr. GEORGE MOORE, in referring to the textile industry in Lancashire, said he did not know a single manufacturer or spinner who wanted, or who used the metric system; but he knew there were a few merchants in this country, who did not weave or spin, but who imported European yarns into this country, and agitated for Parliament to make the metric system compulsory, so that German and French yarns could be introduced into England, whereas Lancashire people wanted to sell Lancashire cloth and yarn out of the country. Lord Belhaven had stated that an International Conference was held in Paris in 1900 for the purpose of simplifying the number of yarns, but he did not state that it was the fifth International Conference which had met since 1870, and that the Conferences had come to five different decisions. At the present time the English system of textile numbering was universal. One of the greatest arguments used by the advocates of the metric system was that an international system was required; they had it in the textile industry. He had been to the United States twice during the present year to examine the question of weights and measures reform as between England and the United States, and was therefore exceedingly surprised to hear Mr. Siemens state that the same measures were not used in this country as were used in the United States. The only different measure in use in America compared with England was the measure of capacity, the Americans still using the old ancient Anne gallon, which England discarded nearly 100 years ago. Mr. Siemens had also stated that James Watt conceived the idea of the metric system, and was in favour of its use. James Watt was in favour of the metric system, but was strongly opposed to the metre. A good deal had been said to the effect that, once people used the metric system, they never gave it up. During the last few years Messrs. Willans and Robinson, of Rugby, had been held up as the leading firm of manufacturers in this country using the metric system, whose example should be copied by the other manufacturers of the United Kingdom. He had received a letter from that firm, dated November 27th, 1906, stating that they would be glad to join the British Weights and Measures Association with the object of assisting in the fight they were making against the compulsory introduction of the metric system into this country. They were satisfied, after a long practical trial, that such advantages as were to be obtained by the use of the metric system in an English machine-shop were too dearly purchased. In the ordinary way they were making new lines of work to English dimensions, and were satisfied that the adoption of the metric system had cost them a great deal in gauges and special tools without affording an adequate return. Messrs. Sellars and Co., the Whitworths of America, after giving the metric system a thorough trial had also come to the same conclusion and were strong supporters of the British Weights and Measures Association, which had for its object strenuous opposition to the compulsory adoption of the metric system.

Dr. FREDERICK ROSE stated that one objection made to the metric system was that the multiplicity of new terms would prove very confusing. Germany had used the metric system for forty-three years, and, as a matter of fact, only a few terms were used. In the measures of length, only the metre, the centimetre, and the millimetre were practically used, the further sub-divisions above or below being scarcely ever used. In capacity, the principal measures were the litre and hectolitre, and for the subdivisions below it was only necessary to say half litre or quarter litre. It was most remarkable that in many parts of Germany the old local names for measures were still retained, when a pound of goods were asked for, 500 grammes being given, and so forth. He also took exception to the way in which the tables of population in favour of the British measures had been tabulated. Looking at the question from an educational point of view, in his opinion the children in the elementary schools of the country were handicapped by having to learn the unfortunate system of weights and measures in vogue, and were behind, compared with the children of other nations, one or one and a-half years in their education.

Major E. H. HILLS, R.E., C.B., remarked that advocates of the metric system in the course of their arguments lapsed almost insensibly into an argument in favour of the decimal system. The author had quite rightly pointed out that the two should be most rigorously distinguished. Almost all the arguments which had been used in the course of the discussion in favour of the metric system, were equally capable of being applied in favour of the introduction of a decimal system based on the English weights and measures. The only argument which remained was that of uniformity with the rest of the world. For instance, the argument used with regard to the waste of a child's time in education, had nothing to do with whether the child learned metres or yards as the unit; it had to do with our complicated system of weights and measures, which they were not concerned to defend in all particulars. He thought the argument in favour of the present free system, where everybody was allowed to use those weights and divisions which most suited their particular trade, was the best for a free country. For scientific purposes, there was no doubt that the decimal metric systems presented very great advantages. If the textile industry was against the change that was quite enough to render it altogether out of the question, because one-sixth of the population of England depended for their livelihood upon that trade; and even supposing it were desirable on other grounds such a change could not be arrived at in the face of the determined and united opposition of so large a proportion of the population and wealth of the country.

Mr. EMERSON DOWSON did not think sufficient attention had been given to the evidence given by Sir Robert Giffen before the Select Committee in 1905 as to the enormous extent of English foreign trade with countries using metric weights and measures. Sir Robert gave it as his deliberate opinion that great loss was suffered by the traders of this country on that account. He thought the comparisons of population which had been given were misleading, and considered it would have been a fairer method to adopt if the figures had been based on the trade that was done with the various countries enumerated.

Mr. R. K. GRAY said the assumption was often made that only the metric system was used in France and other countries. He was the managing director of a company employing 900 men in France and about 3,000 in England, and from personal experience he would like to state in the most positive manner that it was a great mistake for any Englishman to believe that the metric system was solely employed in France. For instance, if anyone went to the market-place he purchased things by the litre; but wine was sold by "le barrique" (225 litres); "le feuillette" (134 litres), "le demi setier" (¼ litre), and "le chopine" (½ litre). People who were not accustomed to the terms of the country did not know what they meant. The old term of the barrel was still used because the barrel was the most useful size for the trade in wine. The same remarks applied even to Government departments. He remembered asking a clerk in the Post-office how much a registered letter would cost, and received the reply—"Fifteen," meaning fifteen sous. The proper answer for the clerk to have given, would have been 75 centimes, but he talked in sous, because it was far more convenient. In the practical application of the measures in France, the people could not detach themselves at all from the natural selection of the proper measures for certain trades. If what he said was correct, why should the people of England make compulsory measures which, in the country of their origin, were not actually in use to-day in common life, although it was 112 years ago since they were inaugurated?

Sir CHARLES WATSON, in reply, said the statement had been made that, in the education of children a great deal of time was wasted in teaching them weights and messures. An American had very carefully taken out from the school schedules in the United States the exact time that was devoted to weights and measures, and found that in a school curriculum of eight years, 6 8-10ths weeks were devoted to the subject, and thereupon said he could not understand how, out of seven weeks, a year could be saved in the education of a child. The measures in the United States were exactly the same as in England with the exception of the gallon. In former times, two gallons were used in England, one for dry measure and another for liquid measure. England retained the dry measure gallon and made that her sole standard, while America adopted the liquid measure as her standard.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Sir Charles Watson for his interesting paper, and the proceedings terminated.

Mr. W. TERTIUS ROWLETT (Leicester) writes:—I am sorry that the lateness of the hour prevented me from taking part in the discussion on the metric system last evening, and shall be obliged if you will allow what I had to say to appear in the *Journal.*

The meeting in 1900, at Paris, of the International Association for the Unification of Yarn numbers, was alluded to by some of the speakers. I am a member of the permanent committee of that Association, and took an active part in the meeting at Paris. The decision was in favour of the metric numbers of 1,000 metres per kilogramme and per number, and the general opinion was that the only hindrance to its adoption was the abstention of Great Britain and America. I advocated that, by way of preparation, every spinner should put the metric number by the side of his own special number on every ticket and invoice; because during forty years' experience I have never found a foreign spinner who did not understand metric counts, whilst most British spinners were ignorant of them. The author spoke of the textile industries, and especially the silk trade, as not having adopted this system; but he was apparently unaware that the British Silk Association, in 1902, joined with all other countries in accepting the international numbering of 1,000 metres per kilo and per number for silk yarns, and added to the convention many suggestions that, when other numberings were used, their metric equivalent should appear also.

The gentleman who spoke on behalf of the cotton trade stated that all the textile traders of this country were opposed to the adoption of the metric system; but this is a mistake, as he is only entitled to speak for the cotton branch. Many of the other branches would welcome the change, as it would obviate the necessity of making goods to two different standards, and allow articles to be used for export without having to be made specially.

It seems somewhat singular that the cotton trade, which uses decimal calculations more than any other branch, should object to the introduction of the metric system, but they give the following reasons:—

Many say their numbers are so well known throughout the world that there is an advantage to keep them; they further say it is impossible to spin metric counts on their machines; but this is quite erroneous. It is absolutely impossible for anyone, even with the very best machinery, to spin exactly to the count required, and therefore a variation of ¼ number above or below the count is accepted. This makes a variation of half a number, which is a much greater difference

than would be necessary in transferring Manchester counts into metric ones. In some cases the existing numbers have almost their exact equivalent in metric sizes; for instance the Manchester

No. 10 = 16·928 metric,	say 17,	a variation of	0·072.
No. 13 = 22·007	,, 22,	,,	0·007.
No. 16 = 27·072	,, 27,	,,	0·028.
No. 18 = 30·471	,, 30½,	,,	0·029.
No. 19½ = 33·011	,, 33,	,,	0·011.

As to the advantage they gain, the foreigner is verging more and more towards the metric numbers. In the present year, I was speaking to a German cotton spinner about English numbers; he did not understand them, but when I mentioned metric sizes, he knew at once. The only change necessary for a cotton spinner would be in reeling his hanks 1,000 metres, instead of 840 yards; or if they were found too heavy, then in half banks of 500 metres. But this would only be required for yarns in bundles, as a very large proportion of the exports are sold in cops, the form in which yarn leaves the machines.

The foreigners continue to use British cotton numbers because they buy so much British yarn, but this complicates their calculations very much when casting. The continental cotton spinners are making great strides ahead, and are principally spinning metric counts, and, other things being equal, these will be bought in preference to British yarns, so that our spinners will be likely to feel their competition strongly when the season of bad trade sets in.

With cloth the change to metric measurements is very simple, the only alteration necessary to the loom being the reed or slay, a comb through which the warp threads pass before reaching the shuttle.

The speakers who advocated the decimalization of the inch spoke for lineal measure only, and have nothing to offer in weights, or measures of capacity, with a decimal relation to the inch. The British Weights and Measures Association, which is the centre of this agitation, in order to retain the inch and pound avoirdupois, propose that the weight of a cubic inch of water should be called 1 ounce, 28 ounces would then weigh 1 pound, and 10 pounds to the gallons, but at the very outset this proposition breaks away from a decimal system. The only complete decimal system in use still remains the metre one, and the attempt to introduce any other system instead, would cause at least as much difficulty.

Mr. AUGUSTE M. THIERRY writes:—It was rather a pity that Sir Charles Watson in an otherwise excellent paper on the past history of the metric system threw cold water on a committee of savants which certainly comprised some of France's finest intellects of the time. It was natural that speakers in the National Assembly should with all their might push the new order of things, and, considering the times, there was no indecent haste in endeavouring to replace the chaotic system of measures of an infamous past.

The author referred several times to the decimal division being the only one applicable to the metric system, but this is not so, for ½'s, ¼'s, ⅛ths, $\frac{1}{16}$ths can be just as easily employed, and in fact are so. Then as to the cubing of 8 being easier than that of 10. Surely this is an error of the author, for nothing could be easier than tens to deal with in this connection.

It was mentioned by Sir Charles that none of his metric friends could give him "the cube or capacity of an hectolitre." I am sorry, for a simple calculation reveals it at once:—

Cubic metre = 1,000 litres.
Hectolitre = 100 do.

therefore the capacity of the hectolitre is the 10th part of a cubic metre or 100 cubic decimetres.

He said the prefixes deca, hecto, kilo, could be mixed up with deci, centi, milli; I can only say that such mistakes are next to impossible, for the former refer to multiples (units), the latter to submultiples (fractions).

I cannot admit that the gain would be all in favour of the foreigner when the change comes; the immense advantage to ourselves is inconceivable for the majority, and hence the antagonism. I venture to say that not twenty in this room use decimal fractions for their computations, and it is only among those that the full understanding of the advantages of the metric system can be self-evident. This is the reason why the permissive act in favour of the metric system is useless; it is a case of the educated minds —a minority—forcing a majority for its ultimate good.

The inch as a unit is utterly impossible, for where are the stepping stones upwards, the multiples 10 inches, 100 inches, 1,000 inches; fancy stating the distance to Land's End in inches! no, this is conservatism walking backwards.

Mr. R. K. Gray referred to old French names of measures being used to this day in France, thereby leading one to infer that the metric system was ignored there in many places, but he did not say that the old names applied to the new measures, and therefore they did not in any way destroy the value of the existing metric system there.

Mr. BENNETT H. BROUGH writes to supplement Mr. Gray's remarks on the persistency of the old units in France, by directing attention to the official circular recently issued by the French Minister of Commerce, a translation of which appeared in the current issue of the *Engineering Magazine* (p. 268). It showed that the penalties imposed by the Act of 1837 had not proved sufficient to prevent the use of the old units, and contained a pathetic appeal that metric units should be used. In Great Britain, where the use of the metric system was permitted by Act of Parliament, it seemed unsportsmanlike that the metric advocates should desire to have all who did not accept their views, fined or imprisoned. Every gaspipe would have to be torn out of our houses; all existing technical literature would be rendered useless; every retail trader would have to buy a new set of weights;

and the working man would be fined or imprisoned if he asked for the half-pint to which he was accustomed. The writer had had experience in mine surveying work in Germany, and even there old units persisted. Shafts were measured in Lachters of 6 feet; horizontal lengths were measured with centimetres on one side and, for actual use, Hanoverian feet on the other, and the compass used was graduated into 24 hours, eighths, and sixteenths of eighths, so essential for rapid work was the principle of continual bisection, which was the basis of practical geometry and of mechanical engineering practice.

TRADE WITH INDIA.

II.

EXPORTS OF INDIAN MERCHANDISE.

While imports of merchandise increased by 6·6 per cent., the value of the exported merchandise increased by only 2·66 per cent., or 410 lakhs, but this followed larger increases in past years. Indian exports consist mainly of raw agricultural products, and in these there is a continual rise and fall, following on prosperous or adverse seasons. Rice represents 63 per cent. of the total value of food grains exported from India, and 11·8 per cent. of the value of all Indian produce. In 1905-6, the total exports of rice to foreign countries receded by 13 per cent. in quantity, but only 4·9 per cent. in value, the exportable surplus of rice depending on the success or failure of other food crops throughout the country. Japan is the largest purchaser of Indian rice, Ceylon and the Straits Settlements coming next. Of the western countries, Germany would seem to be the foremost purchaser.

On the average of the last five years, the value of the wheat exported has represented 39 per cent. of the exports of all food grains, and 6·4 per cent. of the total value of all merchandise exported. The crop of 1905-06, more particularly in the United Provinces, was very seriously injured by frosts, and the effects are very clearly marked in the contraction of the exports to less than half the figure attained in the previous year. It is important to note that in 1904 India was the largest contributor to the wheat supply of the United Kingdom. But in 1905 it fell back into the third place, Russia and Argentina being first and second. The British crop, too, rose considerably in 1905. The shortage in wheat and enhancement in prices necessarily restricted the exports of wheat flour.

Passing by provisions and spices, we come to tea, a produce of special interest to us at home. The area under cultivation has almost doubled within the last quarter of a century, and the out-turn is now over 222 million lbs., 90 per cent. of this being derived from Bengal and Assam. The ascertainable production has increased much more rapidly than the area, 210 as against 85 per cent., in addition to which is to be taken into account the quantity consumed in the country itself, which is supposed to amount to 7 million pounds per annum. The quantity exported in 1905-06, about 884 lakhs of rupees in value, represents a record. From another point of view, it is interesting to note that the joint stock capital engaged in the industry amount to over 14 millions sterling, about £12,000,000 being registered in England and £2,250,000 in India. In addition to this, there is, of course, a large but unknown quantity of private capital also engaged. The labour employed is returned at 552,999 hands, or about one to the acre.

Of this considerable out-turn the United Kingdom still takes the lion's share, (whether for consumption or re-export), though the quantity exported thither (over 166 000,000 lbs.) is less than it was two years ago. On the other hand, the direct exports to Canada have developed from 3·1 to 3·6 per cent. The shipments to Russia have also developed satisfactorily, the general tendency being no doubt in the direction of direct shipments to countries formerly supplied through British ports.

Comparing the progress of the tea trade of India with that of Ceylon and China, the two other principal sources of supply, it is significant that India has increased her exports by 44 per cent. and Ceylon by 55 per cent., while China's exports of black and green tea have declined by 31 per cent., and of brick and dust by 10 per cent.

Manganese ore represents nearly 82 per cent. of the value of all exported metals and manufactures other than hardware, the balance consisting of brass, iron, and copper manufactures. The trade in manganese, which has virtually come into existence in the last ten years, received a great impulse in 1905-6, in consequence of Russian anarchy in the Caucasus and Donetz mines. The exports from India accordingly rose to 316,694 tons, an increase of over 75 per cent. At the same time the price in Europe has gone up by about 50 per cent.

Opium is a product of exceptional interest just now, and it is noteworthy that the exports of the native drug have been continuously declining during the past twenty years, from an average of about 35,000 chests in 1885 to 15,043 chests in 1905. The total value of the exports of opium, both from Bengal and Bombay, decreased by 10·8 per cent. in value, but even now it foots up to 947 lakhs of rupees, which will give an idea of the amount eventually to be made good in the Indian Budget, should the recent anti-opium edict from Peking mean "business," or have any practical effect. As to the unmanufactured tobacco exported from India, this consists largely of leaf intended for "hookah" smoking, and not for manufacturing processes. The British duty is prohibitive as regards this article. Indigo, once a flourishing industry, has decreased to a remarkable extent, as is well known, under the competition of "synthetic" indigo. The drop in value has been from 535 lakhs of rupees in 1895, to 58 lakhs last year, a decline of 89 per cent. Of course, this has been accompanied by a large corresponding decrease in the area under cultivation. Much of the ground

formerly grown with indigo has now been turned over to cotton, which offers a fairly constant market, and to sundry experimental cultures like rubber, flax, &c. Oils (animal, essential, mineral and vegetable) showed a decline during the year under review, the greatest falling off being in mineral oils.

In the group of raw materials, interest naturally attaches to coal. There are 47 companies engaged in coal-mining in India, one in Burma, and the remaining 46 in Bengal. The first coal mine in India was opened in 1820, and for twenty years this solitary mine had no competitors. But with the development of railways, and the establishment of mills and factories, the demand for Indian coal grew apace, while it is yearly taken in greater quantities by ships trading to Indian ports. The increase in output has been steady, and has risen during the past twenty years from 1,294,221 tons to 8,417,739 tons. In twelve months, there was a rise of 2·45 per cent. In 1905-6, the exports exceeded all records, in respect of both quantity and value, Ceylon and the Straits Settlements being the principal buyers.

The export trade in raw cotton is, of course, conditioned by the indigenous crop results, but is governed largely by the relation of textile activity in Europe and the United States to the supplies available in America and Egypt. In these respects, the season of 1905-6 was fairly satisfactory. The area under cotton in India has, in the last three years, increased from 16·5 million to nearly 20·5 million acres. The yield of the crop in 1904-5 had shown a substantial increase, but the crop of 1905-6 diminished by 15 per cent., the condition being specially unfavourable in the Central Province, Berar, Hyderabad, and the Punjab. The American crop was the largest known, and might have been expected to weaken Indian export prices greatly, but the general activity in the textile industries sustained the Indian values better than could have been foreseen. Japan, Belgium, and Germany are all important buyers of Indian cotton, but the increase in exports to the United Kingdom is insignificant.

Some of the most marked examples in the movement of prices in 1905-6, have been furnished by the hide and leather trades. The very great consumption of leather during the Japanese war, and the extensive employment of certain classes of goods in industries now active, have depleted stocks and raised prices 25 to 60 per cent. Although the export of both raw hides and raw skins increased largely in number, the average value of the former rose 6 per cent., while that of skins fell slightly. The value of the two together amounted to 1,011 lakhs of rupees. This represents 6·4 per cent. of the entire exports of Indian produce, and places the trade among the most important. About three-quarters of this came from Calcutta, and of that total the United States took nearly 43 per cent., or 432 lakhs worth, while Germany, Italy, Austria-Hungary, France and Spain followed. The predominance of the United States (when there has been such a shortage in leather supplies as to have created a movement for the abolition of the duties) was mainly in skins.

The exports of jute, on the average of the last three years, represent some 21·8 per cent. of the total value of Indian raw produce exported. During 1905-6 the value exceeded the previous record (that of 1904-5) by no less than 43 per cent. As to the development of the jute industry, it may be mentioned that the number of looms has increased from 6,337 in 1884, when the Indian Jute Mills Association was formed, to about 22,750 in 1906. Of the out-turn, 43½ per cent. came home to England, whence nearly half of that quantity was distributed to other parts of the world. Seeds, such as linseed, rape seed, seamum, cotton, poppy, and castor seed, represent 6·7 per cent. of the entire exports of Indian produce. In 1905-6 their value marked a decline from the very large exports of the previous years. There was an improvement during the year in the trade in all classes of raw silk, which collectively rose 32·4 per cent. in quantity and 13½ in value. A great expansion in shipbuilding and in some other branches of construction in the United Kingdom, Germany, and the United States have synchronised with a contraction in the available supplies of teak, and has induced a rise in prices, in some cases prohibitive. Exports from Burmah to India proper decreased by a further 5·9 per cent., while imports into India from Siam and Java increased by some 34·7 per cent. But practically the whole of the teak trade in the north of Siam is controlled by British companies.

In wool, the general activity of the textile trade caused a rise in the price of the raw material, and an expansion of the Indian exports. These reached 42½ million pounds in 1905-6, which marks a progressive record for the third year in succession. The United Kingdom took 200 lakhs' worth as compared with 174 lakhs in 1904-5.

In the group headed "Articles Manufactured and Partly Manufactured," the most important item is that of cotton manufactures, the exports of which showed extraordinary expansion in response to the restoration of peace in the Far East, the opening of markets rendered bare by a series of unfavourable years, and a return of prices, both of the raw material and of the finished article, to favourable levels. Yarns and piece goods attained in 1905-6 a value of 1,238 lakhs, and 186 lakhs respectively. The figures are unprecedented. Yarn represents about 85 per cent. of the total value, and has shown a substantial increase, corresponding approximately with the estimated rate of increase in the exports of cotton goods from the United Kingdom in 1905. An overwhelming proportion, 94·3 per cent. of this product goes to China; the figures for the Straits Settlements show a slight contraction, which is attributed in the report to the exceptionally healthy state of the trade, and consequent increase of shipment direct to ultimate destination. The export of piece goods increased only about 12·98 per cent., but this is due to no de-

ficiency of demand but to the incapacity of the Indian weaving mills to increase their output commensurately. Grey goods showed healthy progression, the shipments to China being particularly active. But the main markets for Indian cloth are found in East Africa, Aden, Red Sea ports, Abyssinia, the Persian Gulf, Ceylon and the Straits, while dyed and printed cloths go mainly from Madras to the two last and the Philippines. Madras also sends handkerchiefs and shawls to the diminished value of 8½ lakhs, almost wholly to the United Kingdom. In connection with this, one may note the uninterrupted increase in the output of yarn and cloth from the Indian mills, which now boast of 37,454 spindles, the great majority in Bengal. For the first time, it has been possible to compute that the capacity per spindle and loom respectively, under Indian conditions is 131 lbs. of yarn and 3,221 lbs. of cloth per annum.

Exports of jute manufactures, both bags and cloth, increased largely both in quantity and value, the aggregate production having reached a level never before attained. The shortage in the Indian wheat shipments diminished the country demand for bags, and Australasia and Chile took very large consignments, 141 lakhs and 64¼ lakhs worth respectively. In the United States there is a heavy duty on imports of made bags, but of cloth they took 419½ million yards, with a total value of 378 lakhs of rupees, making a quantitative advance of 19 per cent. on the previous year's figures.

Silk and woollen manufactures (the latter chiefly carpets and rugs) declined in value so far as exports are concerned. But the production in woollen mills in India marks a quantitative increase, indicating a strong internal demand. Tanned hides and skins, like the raw articles referred to above, shared in the activity of the leather trade, the values registered in 1905-6 being 154 and 209 lakhs of rupees respectively. The greater part of both comes to the United Kingdom, but in 1905-6 America took a considerably larger share of hides, and Great Britain's proportionate share declined. In regard to skins, the United Kingdom increased her share from 90 to 93·6 per cent., this being ascribed to the demand for motor padding and clothing.

Lac is an article much in demand for electrical and certain other industries, and during the last three years there has been a marked upward tendency both in quantity and in value exported. Shellac, buttonlac, and the raw material (stick and seed lac) have all participated in the expansion. The United States appears as the first buyer of lac from India.

Viewing, in conclusion, the general distribution of the export trade, we find of course the United Kingdom in the premier position, with 25·3 per cent., China coming second with 13½ per cent., and Germany, the United States, Japan, France, and Belgium next. Then follow the Straits Settlements, Ceylon, Italy, Austria-Hungary, and Egypt, the last having fallen to the lowest place in 1903-4, in consequence of the change made in crediting to the countries of final destination, instead of to Egypt, the large shipments of produce, principally rice and wheat, originally consigned to Port Said to await orders for delivery.

THE NORWEGIAN PAPER INDUSTRY.

The modern paper industry of Norway may be considered to date from the same period as the chemical pulp industry, that is to say about the year 1880. Although writing paper has been manufactured in that country for one hundred years, the quality of the article produced is not of the best, and the finer grades of such paper are therefore still articles of import. Rags are largely used in the mills producing writing paper. It is in the manufacture of printing, news, and wrapping papers that the Norwegian mills excel. The wood employed in the mills excel. The wood employed in the mills is mostly spruce. Connected with the paper mills is generally found a sawmill, where the butts of the large trees are sawn to lumber, while the tops, branches, and small trees which have been cut to thin out the forests, go to the pulp and paper mills. According to the American Consul-General at Christiana, both mechanical and chemical pulp are used by the Norwegian paper mills. The pulp is reduced to an even, consistent mass, containing about 60 per cent. of water, and conducted into a receptacle where sizing is added; thence through the paper machine, where it is evenly distributed in a thin layer on a wide endless belt, which passes through a system of hollow horizontal rollers. These rollers are heated by steam; they are placed side by side, with very little space between, and turn on their own axis on a vibrating metal frame. The belt holding the layer of pulp is carried along by the rollers, and the thin mass dries very rapidly. The width of the paper is determined by dividing belts, placed on each side of the main belt or bed, holding the unfinished paper. The dividing belts may be set apart for any desired width of paper. When the paper is dry, it is finally passed between two cloth-covered rollers, where it is given finish and lustre; thence between another set of warmed rollers, which completes the operation. As the paper escapes, it is received on a revolving reel and cut in the desired lengths. Trial has been made with Canadian spruce, which was sent over, and used in a Norwegian paper mill for experimental purposes. The Norwegians claim that their own wood is superior for the reason that it holds less resin than the Canadian. The mills at Skien employ about one thousand hands; they have eight machines, and turn out about 35,000 tons of paper annually. Norway possesses a number of valuable water powers, well distributed through the timbered districts. Transportation facilities are good, and wages low. The paper machines used are partly of home manufacture and partly imported, a considerable number coming from Germany.

HOME INDUSTRIES.

Watches and Plate.—Are watches plate within the meaning of the Customs Act, 1842? If so, they must be assayed, stamped, and marked before they can legally be sold, or exposed for sale, within the United Kingdom. Since the passing of the Act of 1842 finished foreign watches have never been treated as coming within the designation of plate, nor was it ever suggested that watches were liable to the duty as plate, which was not repealed till 1890. But last year the Goldsmiths' Company raised the question as to whether finished watches are covered by the word "plate" in the Act of 1842, and, in order to have the question settled, bought four watches, two of them in gold and two of them in silver cases. All admittedly were of foreign manufacture. The case was tried before Mr. Justice Channell, who decided against the Goldsmiths' Company. There was an appeal, and last week the Court, consisting of the Master of the Rolls, Lord Justice Cozens-Hardy, and Lord Justice Farwell, reversed Mr. Justice Channell's ruling. Sir Robert Finlay (who appeared for the defendants) had argued that no one would use "plate" as including gold and silver watches in common parlance. The Court of Appeal did not dispute this, but said "the question is not of the meaning of the word 'plate' in ordinary language, but in Acts of Parliament, where it undoubtedly includes gold and silver watch cases," a point, by the way, not denied by Sir Robert Finlay. "Perhaps," he had argued, "a large collection of watch cases might come within a digest of plate, but finished watches would certainly not come within the expression 'plate.'" Sir Robert Finlay contended again that it was much in his favour that, since the passing of the Act of 1842, finished watches had never been treated as coming within the bequest of plate; and Mr. Justice Channell thought that considerable weight ought to be given to what had been the uniform practice since the passing of the Act by those who had to administer it. But the Court of Appeal do not seem to have attached much weight to this argument, which to the layman may seem strong. When there was a dispute as to the meaning of a word occurring in an Act of Parliament more than 60 years old, said Sir Robert Finlay, the *contemporanea expositio* threw light on the question, and was rightly taken into consideration. But the Court of Appeal felt that "the principle of *contemporanea expositio* cannot be applied to so modern a statute as the Customs Act of 1842. When there are ambiguous expressions in an Act passed one or two centuries ago, it may be legitimate to refer to the construction put upon the expressions throughout a long course of years by the unanimous assent of all parties interested, as evidencing what must presumably have been the intention of the Legislature at that remote period," but an undisputed interpretation only 63 years old is, in the opinion of the Court of Appeal, entitled to no such weight. And to the further argument that traders have embarked in business—as they unquestionably have done—on the strength of this usage the Court of Appeal answered that this usage "is not supported by any facts set out in the special case, and would be disposed of, if alleged, by Feather v. Queen." The Court held therefore that Mr. Justice Channell's judgment must be discharged. There will no doubt be an appeal to the House of Lords. A very large business has been built up in consequence of the practice that has prevailed, and it is most important to the watch-making industry to have that final interpretation of the law on the subject which can only be got from a decision of the House of Lords.

Publicans and Licenses.—What is known as the Leeds judgment—delivered on November 8th, by a Court composed of the Lord Chief Justice, Mr. Justice Ridley, and Mr. Justice Darling—has had a most disturbing effect upon licensing justices and publicans, and on Tuesday the Government introduced a short Bill, which is of course retrospective, to make clear the law. The facts are not in dispute. The Leeds magistrates resolved to extinguish the licenses of fifteen public houses as unnecessary, and this involved compensation under the Act of 1904. Against this decision, "the trade" appealed on the ground that the tribunal, which had refused to renew the licenses was unlawfully constituted. The Act of 1904 requires that in county boroughs, of which Leeds is one, the licensing authority shall be the whole body of justices, unless they delegate their powers to a committee. But this was not done at Leeds, though there was a body popularly called the licensing committee. Consequently the whole body of justices should have dealt with these licenses, whereas they were adjudicated upon by a small minority. The Court of King's Bench held that "the trade" was in the right in their view of the law, or if not that there must be "at least a majority" of the justices present, which was not the case at Leeds. Unfortunately the magistrates were not represented at the hearing in the King's Bench, the reason being that they would have had to pay the legal expenses out of their own pockets, which seems strange having regard to the general practice in similar matters. Be that as it may, the judgment has had far reaching effects. There is the further question, whether the legality of the arrangements for the administration of compensation funds is not involved. The Chief Constable of Bradford is taking legal advice with reference to the control of licensed houses, and fourteen Bradford brewers are about to apply for an injunction to prevent payments out of the compensation funds except under an order from the Court, and at the same time return of publicans contributions is to be demanded. The chairman of the Manchester licensing justices (Sir T. Thornhill Chance) in a letter to the Home Secretary, says that the real importance of the decision is its obvious effect on the legality of the compensation fund already established. "In January, 1905, the justices imposed charges for the establishment of

the fund, and the sum of £30,000 was paid into the fund by license holders on that account, and the whole of this sum has been paid away." Similar charges were imposed in January, 1906, and have been collected. There was not a majority of the justices present when the charges were imposed. There are about 200 qualified magistrates on the Manchester Board, and to secure the attendance of at least 101 justices would be practically impossible. The Government have recognised the seriousness of the position created by the decision of the High Court by the promptitude with which they have brought in a Bill to make the law clear.

Home Work by Employés.—The Home Secretary has addressed a letter to each of the City and Borough Councils of London, urging them to more vigilant enforcement of such provisions of the Factory and Workshop Act, 1901, as relate to home work by *employés*. Mr. Gladstone points out that outworkers are the weakest section of the labouring class, and the class in respect of which the State, from the nature of the circumstances, is least able to control the conditions of the work. If, therefore, it is to be effectively controlled, the local authorities must make a full use of their powers. Herein lies the difficulty. The Act of 1901 gives full powers to the local authorities, but these powers are often permissive only. Section 112 of the Act enacts that if any manufacture, process, or description of manual labour, which in pursuance of the Act, has been certified by the Secretary of State to be dangerous, is carried on in a domestic factory or workshop, all the provisions of the Act shall apply as if the place were a workshop other than a domestic factory or workshop. The local authority may take the necessary steps to put an end to the state of things complained of, but does not appear to be bound to do so. Thus, Section 110 enacts that "if any inmate of a house is suffering from an infectious disease to which this Section applies, the District Council of the district in which the house is situate may make an order forbidding any work to which this section applies to be given out to any person living or working in that house or such part thereof as may be specified in the order, and any order so made may be served on the occupier of any factory or workshop, or any other place from which work is given out, or on the contractor employed by any such occupier;" but though the section gives the power to the local authority it is not mandatory. There are obvious difficulties in the way of making it so, but the permissive character of the law as it applies to the outside worker makes such injunctions as that just issued by the Home Secretary very necessary in cases where the local authority is apathetic or indifferent.

Shipping Rings and the Government.—The Government have appointed a Royal Commission, of which Mr. Arthur Cohen, K.C., is chairman, to inquire into the operation of shipping "rings" or conferences generally, and more especially into the system of deferred rebates, and to report whether such operations have caused, or are likely to cause injury to British or Colonial trade, and if so, what remedial action should be taken by legislation or otherwise. This Commission has been asked for for some years past, and the evidence it collects will enable judgment to be formed upon a highly controversial matter. If shippers and importers are to be believed there are shipping "rings" in existence which are highly detrimental to British trade, favouring the foreigner at the expense of the British producer. The shipowners, and others concerned on the other side, are equally positive in their denials of unfair treatment.

Canals.—The Royal Commission on Canals and Waterways has taken the unusual but convenient course of publishing a mass of evidence before the conclusion of its investigation and the preparation of its report. It has examined 54 witnesses, and apparently completed its investigation so far as England is concerned, but has still to inquire into the systems of Scotland and Ireland. The evidence now available brings home the complexity of the subject and the difficulties of the problem to be solved. All the witnesses are in substantial agreement that the larger canal systems are performing very useful services in facilitating inland transport, but the witnesses are equally agreed that many of the waterways now derelict cannot profitably be restored. The evidence points to the conclusion that a canal is most profitably employed to connect an inland industrial centre with a seaport, and to establish direct water communication for the export and import traffic of the manufacturers. It follows that the canals which would probably give the best return for capital spent upon them are those which lie between seaports and centres of manufacture. But the difficulties in the way of improvement are many and serious, and the suggestions of the Commission as to how they are to be overcome will be awaited with interest. Not the least of the difficulties is the variety of ownership and control. The same canal is owned at different places by different companies, with different tolls and different gauges. Though there are nineteen through routes by water in England and Wales there is not one which has the advantages enjoyed by each of the railways with which they compete, of being under a single body. As the authors of "Our Waterways" have pointed out, on the three routes, connecting London and Liverpool, there are, including the authorities of navigable tideways, such as the Mersey, Severn, and Humber, twenty-six different bodies—and were until 1894, twenty-eight—which compete with each other; and there are twenty-seven on the four routes between London and Bristol, ten on the three between Birmingham and Bristol, and the same number on the three between Hull and Liverpool. And so with the gauges. On the shortest of the last-named three routes, a consignment of goods has to traverse ten

different waterways, the gauges on the locks of which range through various grades, from 50 feet by 14 feet by 4·6 feet on Sir John Ramsden's canal, to 212 feet by 22 feet by 9·6 on the Aire and Calder. The sectional area of the latter canal again is 475 square feet; that of the Trent and Mersey, 136 square feet; and that of the Weaver navigation, 780 square feet. Some of the witnesses examined by the Commission are of the opinion that, given greater facilities for amalgamation, private enterprise may bring about unity of control, but whether it would be possible to bring large systems under one management without the intervention of the State is questioned by the authorities. And any such intervention would be beset by obstacles. It was, however, strongly advocated by Mr. Lloyd and Mr. Abernethy before the Select Committee of 1883, while the proposals for its adoption made by the Associated Chambers of Commerce were only abandoned in favour of those for establishing a Canal Trust on account of the difficulty of persuading Parliament to provide the funds necessary for carrying it out. It is also to be borne in mind that the ownership of canals by the State has produced successful results in India, and throughout the continent of Europe.

GENERAL NOTES.

Cocoa and Grenada.—The absence of fluctuation in the yield of cocoa plantations has been so often adduced in favour of cocoa cultivation, and Grenada owes so much to the cocoa tree, that it may be noted that they suffered considerably from the shortage of the crop, which was some three thousand bags less than for the previous year, whilst prices fell heavily, thereby adding to the difficulties of the situation. In his report (Cd. 2684), the Governor, Sir N. B. Llewelyn, attributes the shortage of the crop in large part to unequal incidence of rainfall during the year, and these unsatisfactory prices were indirectly attributable to the largely increased influx of West African cocoa into the market, which seriously affected the sale of the lower grades of West Indian cocoa. Fortunately, there is every indication of continuance in the present increase of consumption, and it is a little surprising that those young Englishmen with capital at their command, and acquainted with country life, do not try cocoa cultivation in the West Indies. It offers pleasant possibilities to the young, energetic, and up-to-date agriculturist.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday Evenings, at 8 o'clock:—

December 12.—"Fruit Growing and the Protection of Birds." By Cecil H. Hooper, Member of the Council of the National Fruit-Growers' Federation.

December 19.—"Modern Developments of Flour-Milling." By Albert E. Humphries, President of the Incorporated Association of British and Irish Millers. Professor Thomas Hudson Middleton, M.A., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

December 13.—"The Indian Mohammedans: their Past, Present, and Future." By A. Yusuf Ali, M.A., LL.M. (Cantab.), I.C.S. Lord Ampthill, G.C.S.I, G.C.I.E., will preside.

January 24, February 14, March 14, May 2, 30.

Applied Art Section.

Tuesday evenings, at 8 o'clock:—

December 18.—"Basket-Making." By Thomas Okey. Lewis Foreman Day, F.S.A., will preside.

January 29, February 19, March 19, April 30, May 28.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 15, March 5, April 23.

Papers to be read after Christmas:—

"The Straits of Panama." By Philippe Bunau-Varilla, formerly Chief Engineer of the Panama Canal Company.

"The Principles and Practice of Insurance, and their modern Developments." By Thomas Emley Young, B.A., Past President of the Institute o Actuaries, and Past Chairman of the Life Offices Association.

"Smoke Prevention in Factories." By John B. C. Kershaw, F.I.C.

"The Underground Water Supply of the Thames Basin." By Clayton Beadle.

"Engraving and Photogravure." By. J. Craig Annan.

"Mediæval Stained Glass, its Production and Decay." By Noel Heaton, B.Sc.

"Cold Storage and Food Supply." By Hal Williams.

"Modern Typewriters and Accessories." By Arthur E. Morton, Examiner in Typewriting to the Society of Arts.

"Motor Omnibuses." By Lord Montagu of Beaulieu.

"Apprenticeship." By James Parsons, M.A.

"Artistic Treatment of the Exterior of the Pianoforte." By William Dale, F.S.A.

"Joinery and Cabinet Making." By A. Romney Green.

"Oils, Varnishes and Mediums." By ARTHUR P. LAURIE, M.A., D.Sc., F.R.S.E.

"Sheffield and Electro-plate." By SHERARD COWPER-COLES.

"The Progress of the Uganda Protectorate." By G. WILSON, C.B.

"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G.

"The City of Madras." By SIR JAMES THOMSON, K.C.S.I.

"The Applicability to Indian Rivers of the Italian System of dealing with Silt." By SIR EDWARD C. BUCK, K.C.S.I.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

A. D. HALL, M.A., Director of Lawes Agricultural Trust, "Artificial Fertilisers: their Nature and Functions." Five Lectures.

LECTURE IV.—DECEMBER 10.—*Phosphatic Fertilisers.*

LECTURE V.—DECEMBER 17.—*Potassic Fertilisers. Consumption of Fertilisers.*

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

January 28; February 4, 11.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

JUVENILE LECTURES.

Wednesday afternoons, January 2 and 9, 1907, at 5 o'clock.

"Perils and Adventures Underground." By BENNETT H. BROUGH.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 10...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. D. Hall, "Artificial Fertilisers: their Nature and Functions." (Lecture IV.)

Farmers' Club, Whitehall-court, S.W., 6 p.m. Mr. H. Trustram Eve, "Freedom in Farming, with special reference to Selling off Produce."

University of London, South Kensington, S.W., 8 p.m. Mr. Banister Fletcher, "Greek Temples of the Corinthian Order."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. L. S. Wood, "The Improvement of our Woodlands."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Major J. H. Bealom, "Irrigation in the United States."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Review of Professor Flanders Petrie's work on "Sinai," by the Secretary.

London Institution, Finsbury-circus, E.C., 5 p.m. Rev. J. Stephen Barras, "The Churches of the City."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates Section.) Mr. A. B. Symons, "Up-to-date Milling Machines."

TUESDAY, DEC. 11...Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. G. Pinches, "The Tablet with Cuneiform Text from Yuzghat."

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Dr. A. C. C. Cumming, "The Electrochemistry of Lead." 2. Dr. A. C. C. Cumming, "Contributions to the Study of Strong Electrolytes." 3. Mr. R. W. Vicarey, "Storage Batteries aud their Electrolytes" (Part II.).

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on following papers:—"The Talla Water-Supply of the Edinburgh and District Water-Works;" "Repairing a Limestone-Aqueduct;" and "The Yield of Catchment-areas." 2. Mr. H. W. E. Le Fanu, "Mechanical Considerations in the Design of High-Tension Switch-Gear."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Optical Society, at the British Horological Institute, Northampton-square, E.C., 8 p.m. Dr. C. V. Drysdale, "The Evolution of Artificial Lighting."

Photographic, 66, Russell-square, W.C., 8 p.m. Dr. W. J. S. Lockyer, "Thunder Storms and a Camera."

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. A. W. a'Beckett, "The Colonial Press."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, DEC. 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Cecil H. Hooper, "Fruit Growing and the Protection of Birds."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, DEC. 13...SOCIETY OF ARTS, John-street, Adelphi, 4½ p.m. (Indian Section.) Mr. A. Yusuf Ali, "The Indian Mohammedans: their Past, Present, and Future."

Royal, Burlington-house, W., 4 p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Junior Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Mr. Matthew Webb, "Gesso-work."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. J. W. Jenkinson, "Tadpoles—a Study in Embyology."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, DEC. 14...Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. A. Carmichael, "Mechanical Improvements in the Drainage of the Bedford Level."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Lace."

Astronomical, Burlington-house, 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Conclusion of discussion on Mr. Thomas Clarkson's paper, "Steam as a Motive Power for Public Service Vehicles." 2. Mr. Henry Fowler, "Lighting of Railway Premises: Indoor and Outdoor."

Journal of the Society of Arts.

No. 2,821. VOL. LV.

FRIDAY, DECEMBER 14, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 17, 8 p.m. (Cantor Lectures.) A. D. HALL, M.A., "Artificial Fertilisers: their Nature and Functions." (Lecture V.)

TUESDAY, DECEMBER 18, 8 p.m. (Applied Art Section.) THOMAS OKEY, "Basket-making."

WEDNESDAY, DECEMBER 19, 8 p.m. (Ordinary Meeting.) ALBERT E. HUMPHRIES, "Modern Developments of Flour-Milling."

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 2nd and 9th, at 5 o'clock, by BENNETT H. BROUGH, F.G.S., F.I.C., F.C.S., on "Perils and Adventures Underground."

Each Member is entitled to a ticket admitting two children and an adult. A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received. Members who desire tickets for the course are requested to apply for them at once.

CANTOR LECTURES.

On Monday evening, 10th inst., Mr. A. D. HALL, Director of the Lawes Agricultural Trust, delivered the fourth lecture of his course on "Artificial Fertilisers: their Nature and Functions."

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 13th, the Right Hon. Lord AMPTHILL, G.C.S.I., G.C.I.E., in the chair, the paper read was—"The Indian Mohammedans: their Past, Present, and Future." By A. YUSUF ALI, M.A., LL.M. (Cantab.), I.C.S.

The paper and discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 12th, 1906: SPENCER PERCIVAL UMFREVILLE PICKERING, M.A., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Bainsmith, Mrs. Georgina, Fairholme, St. Ives, Cornwall.
Cuthbertson, Ebenezer, 33, Arncliffe-gardens, West Hartlepool.
Fletcher, Mrs. Esther, Ashville, Stourbridge.
Flurscheim, A., Chancery-lane Station-chambers, 31, High Holborn, W.C.
Habell, Frank Stannah, care of Messrs. W. Hill and Co., Elderslie Rock Blasting, Renfew, near Glasgow.
Higgins, Eric, 5, Oak-terrace, Fairfield, Liverpool.
Honey, Richard, International and Mortgage Bank of Mexico, Mexico City, Mexico.
Honey, Thomas P., International and Mortgage Bank of Mexico, Mexico City, Mexico.
Ibbs, Miss Edith A., 3, Endsleigh-gardens, N.W.
Keen, Walter Henry, Portland-lodge, Atkins-road, Clapham-park, S.W.
Raegener, Louis C., 141, Broadway, New York City, New York, U.S.A.
Roberts, James, 1, Paper-buildings, Temple, E.C.
Shafi, S. M., 54, Poonamallee High-road, Parktown Post, Madras, India.
Street, Arthur William, 37, Hamilton-square, Birkenhead, Cheshire.

Thompson, Charles, 11, Norfolk-street, Strand, W.C.
Wilson, George, C.B., Hans-crescent Hotel, Hans-crescent, S.W.

The following candidates were ballotted for and duly elected members of the Society:—

Blake-Thomas, Hugh, Cawsand, Pwllheli, North Wales.
Bradley, Benjamin Lawrenson, Barn-ith Wood House, Grindleford, Derbyshire.
Middleton, Robert Hugh, 26, Selborne-road, Ilford, Essex.
Muntri, Kashinath Gorindjee, 192, Worlee, Bombay, India.
Shaw, Mrs. W. T., Hypatia-lodge, Percy-villas, Campden-hill, W.
Smith, Harry E., Wrexham-house, Winn-road, Lee, S.E.
Stewart, James Ernest, care of The Pekin Syndicate, Limited, Tientsin, China.
Wilberforce, Professor Lionel Robert, 5, Ashfield-road, Aigburth, Liverpool.
Wild, Albert Edward, 30, Westbourne-terrace, W.

The CHAIRMAN, in introducing the author of the paper, said that when he was asked to take the chair, he felt, in the first instance, considerable diffidence in the matter, because Mr. Hooper was well-known as being allied with the interests of fruit growers. The generally reputed views of fruit growers on the subject of wild birds were very simple, viz., "Kill them all." If that had been Mr. Hooper's views, he (the Chairman) would have felt considerable diffidence in lending any support to them; but a very slight conversation which he had with the reader of the paper showed him at once that Mr. Hooper did not intend to take a one-sided view of the subject, but was going to deal with it fairly and squarely. There was no question that fruit growers had a very serious matter to deal with at the present moment in the shape of wild birds; and as a fruit grower himself in a small way, and as one who had devoted all his energies for some years past to the interests of fruit growers, he was fully aware that the question became more serious every year. For some years past he had been prevented at his own place in Hertfordshire from growing any currants or gooseberries, and at the present time he was engaged in the pleasant occupation of grubbing up 1½ acres of plum trees, which he had carefully tended for the last 15 years, simply because the birds took nearly every bud; and the gross returns on that 1½ acres for the last ten years had not averaged more than £3 per annum. At the same time, although fruit growers had his sympathy, it must be recognised that sympathy was due to the birds also. The fact must not be over-looked that birds did a great deal of good as well as harm; and the fact must also be taken into consideration, that they did good in a way, the money value of which it was difficult to estimate, viz, from a scientific, educational, æsthetic and humanising point of view. But those considerations would have to go to the wall if it became a question between them and the continuation of fruit growing in England, because an enormous amount of capital was invested in fruit-growing, and the livelihood of many men was dependent upon it, while it was one of the few remaining branches of agriculture which was paying and progressive in this country. The gist of the whole question was to find a *modus vivendi*—a "live and let live"—between the fruit growers and the birds; and the first step towards such an achievement was to make themselves more acquainted with the habits of wild birds, to find out which birds were noxious and which beneficial. In that research they looked to gentlemen like Mr. Hooper, who had given a large amount of time and study to the question.

The paper read was—

FRUIT GROWING AND BIRD PROTECTION.

By CECIL H. HOOPER, M.R.A.C.
Member of the Council of the National Fruit Growers' Federation.

When the Council did me the honour of inviting me to read a paper before the Society on this subject I felt tempted to undertake it, but knew the task could have been placed in very much better hands. I have had nearly fourteen years' experience of fruit farming, during which time I endeavoured to notice the action of birds in relation to fruit and other crops; but duly to study the habits and food of our wild birds necessitates much patient and watchful observation of the birds in their haunts during many years, as well as learning to recognise them from museum specimens and books. The habits of birds are taught in making a collection of eggs, by the use of the catapult, by the gun, and the examination of the crops of birds; but the harmless field glass is a great assistance, and photographing birds in their haunts must be most instructive. Passing on to the economic effect of birds with regard to the cultivation of fruit, it is all important that we should be fair and unprejudiced in our study of this vexed question, and it is only after studying the birds by their works that consideration should be given to beauty of song or plumage. The pleasure derived from observing birds, and becoming familiar with their plumage, their notes, and, above all, their habits, is never ending; and the habits and food of the every-day birds might with advan-

tage be taught to the children in more of our village schools.

There are certain birds which are distinctly beneficial to the farmer, fruit grower, and gardener if not allowed to become too numerous; but as soon as their numbers exceed a certain limit they become equally injurious, and cannot be regarded as other than enemies. In this category may be mentioned the blackbird, missel thrush, song thrush, starling, and rook. We need to observe the food of birds for the whole twelve months and for successive years in order to arrive at sound conclusions. Agriculturists and fruit growers admit that birds, as a class, are more beneficial than they are injurious to the cultivator. Yet many of the most common and injurious insects to fruit are eaten sparingly and by few species of birds, whilst there are others that I believe I am correct in saying are eaten by no bird, yet if left unattended kill the plant.

With the introduction of spraying, grease-banding, and other devices to prevent or destroy insects, fruit growers are less dependent on birds for their protection from injurious insects than they were, say, fifty years ago; yet the damage done by birds, in the opinion of old fruit growers, is more severe than at that date. The increase and spread of fruit cultivation probably favours the increase of birds that devour fruit and fruit buds; whilst the close preservation of game destroys the birds which act as a natural check on their undue increase and favours other birds living in the woods, such as the bullfinch and wood pigeon, which are injurious to the fruit grower and farmer, yet are not interfered with by the gamekeeper. Again, the many advantages possessed by the house sparrow in the struggle for existence has enabled it to multiply inordinately, to the detriment of other and more useful birds.

Mr. Radcliffe Cooke considers the enforced attendance of children at school till the age of fourteen, at which time they go to work, by stopping bird-nesting, has had its effect in the increase of small birds. Now that most of the less common birds' eggs are protected by law, children are often afraid to take any, and at many schools the teachers discourage bird-nesting. Far be it from me to depreciate in any way teaching kindness and humanity with regard to beast or bird, yet it probably affects materially the increase of the commoner birds, such as the house sparrow, the blackbird, the thrush, the chaffinch, and the greenfinch, of which in many cases we have too many for the good of those who have to live from the produce of Mother Earth.

Bird-minders must have a gun license, costing 10s.; and so must the farmer if he intends to scare birds, as no one is allowed to carry fire-arms without a license; twenty—or even ten years ago it was hardly thought necessary on a farm to take out a license for a short period of bird-scaring; the effect is that fewer persons use guns than formerly.

Preservation of Hawks and Owls.

Landowners, sporting tenants, and especially gamekeepers should be more merciful to hawks and owls unless actual injury to their birds occurs. A friend in Herefordshire wrote me that the other day he spoke to a gentleman who preserves largely, saying that the sparrow-hawk was the only bird of the kind that was at all destructive to game. He replied: "I don't know one kind from another; all I know is that when I get a chance to shoot a hawk I do so." Again, as to the destruction of owls, some time ago a bird-stuffer in Gloucestorshire told a lady he had sixty skins of owls to stuff. He regretted their destruction, but it was not to his interest to ruin his connection with customers by informing against them. This summer I saw a dead long-eared owl which had been shot in Norfolk by an ex-policeman, apparently merely for the pleasure of shooting at something. It was not even going to be stuffed.

Causes Influencing the Increase or Decrease of Certain Birds.

Among the most evident natural influences that govern the increase or decrease of certain birds are:—

1. Migration, not only from one country to another, but from different parts of our own country.
2. The character and habits of the bird.
3. The quantity of food available.
4. The number of young the birds rear yearly.
5. The capability of the bird to withstand adverse conditions, such as long continued snow and frost.

As an example of birds moving from place to place, blackbirds and thrushes do not appear to diminish noticeably in numbers, though shot or trapped, thus a fruit-grower in Herefordshire, with 100 acres of plantation, drives the blackbirds in the summer in the early morning, with his three sons and a keeper who have shot as many as 70 or 80 in a morning including a few

thrushes, totalling some 2,000 in a year, yet the blackbirds still come every year without much diminution; he has given up growing red currants on account of the birds.

The Boughton Sparrow Club last year reported nearly 6,000 sparrows, but even that number, it was stated, makes no perceptible difference in the number this year.

The thrush family are considerably distressed by long-continued snow and frost, in fact a severe winter; but the blackbird resists the effect of winter better than the thrush because it lives on berries which have fallen off trees, and hunts under the leaves for food. Starlings can take care of themselves in severe weather better than the thrush family. The house sparrow is still more favoured by its audacity, its hardihood, its wide variety of food, and its large progeny.

CHANGE OF HABIT OF BIRDS.

That birds may change their habits we have undoubted example in the kea or mountain parrot of New Zealand, which used to eat nuts, but since the introduction of sheep, has changed to eating fat—first from the butcher's shop, next from dead sheep, and now it pecks through the backs of live sheep.

In conversation with fruit-growers I have been told, after explaining the damage done, this bird used not to do such and such damage; thus the sparrow pinching the flowers of the gooseberry appears to be a habit that is increasing, also its tendency to eat fruit. Mr. O. V. Aplin, in his useful letter to the Central Chamber of Agriculture in reference to birds injurious to agriculture and to fruit-growing, wrote:—

"Some birds have altered their habits in respect of food. The alteration may be owing to the increase in numbers of the particular species which has altered its mode of feeding, or it may be owing to the great increase of some other species. For instance, I am inclined to think that the enormous increase of the starling has caused the rook to alter its food; the starling eats up the animal or vegetable food the rook formerly lived on in the spring, and the rook eats more corn and fruit and has taken to eating partridge and other birds' eggs to make up for it. Ten years ago in this district of Oxfordshire the damage done by birds to the fruit-grower was practically nil. The blackbird now, besides eating bush fruit in increased quantities, eats plums, apricots, pears and apples. Unlike the thrush, which continues its snail and worm diet all the summer (and, I think, eats no more fruit than it used to do), the blackbird from the time the first bush fruits ripen until autumn lives upon fruit. The damage done to plums is a new thing here, and is now most serious.

"The starling used only to eat a few cherries, now it also eats strawberries, currants, plums (even on wall trees), early pears in great quantities, and apples. Almost all this damage is quite a new thing, and it gets worse each year. The blue tit pecks holes in pears and apples to a serious extent. Here it has only taken to this recently; the habit grows year by year."

A writer from Cornwall in the *Field* of November 3rd, 1906, said:

"I have never known it before, but this year the blackbirds have been perfectly ravenous for tomatoes. I have some growing against a wall out of doors, and the birds even pecked through fish net to get the fruit; curiously enough no other birds were seen to touch them. I watched a thrush foraging near a partly eaten tomato and it did not touch it."

Mr. Till, of Eynsford, wrote me that a few years ago his mulberries were comparatively safe, now starlings and thrushes clear the lot —hundredweights are borne by the tree and the birds have all; so with the cherries on big trees that cannot be netted. The field fruit is protected by scaring, so the birds come where they are not and cannot be scared. He contends the game laws are at the bottom of the mischief, and that we are sacrificed that a few may have sport.

THE LEGAL PROTECTION OF BIRDS.

Protection of birds by law is no new thing. If mankind had followed the humane command given through Moses, in Deuteronomy xxii. 6 (viz., not to take both young and parent bird, and if the young are taken to spare the mother bird), many of the birds the loss of which naturalists deplore would still be in existence. In the City of London, in 1555, kites and ravens were protected by law for their value in feeding on garbage of the streets and even of the Thames.

The Report of the Select Committee on Wild Birds' Protection, in 1873, tells us that "while birds of prey are being banished, owing to poultry-keepers and game-preservers, the reclamation of wastes, the enclosure of open spaces, and the greater care bestowed on timber trees by removing those that, being decayed, are much infested by insects, the smaller denizens of the woodlands, gardens, and arable fields are unquestionably more numerous than ever."

THE WILD BIRDS PROTECTION ACTS, 1880 TO 1904

have for their object apparently the protection of the rarer and non-injurious birds

and their eggs throughout the year, and of all the birds during the breeding season. The birds and eggs to be protected are decided on by each County Council, and these appear all to vary, influenced by differences in the mode of agriculture and other considerations.

The general public, other than an owner or occupier of land or person authorised by either, may not take or destroy or incite anyone else to take or destroy any wild bird soever between March 1st and August 1st on pain of a reprimand and payment of costs for the first offence, or 5s. for subsequent offences in the case of non-scheduled birds, and up to £1 fine for scheduled birds, with forfeiture of the bird in both cases. The landowner, the occupier, or persons authorised by either, may shoot or trap any bird not protected in the schedule at any time in the year.

In 1904 the use of the cruel pole-trap, which used to be specially used by gamekeepers to catch owls, hawks, jays, and other birds, was prohibited under a penalty of £2 for first offence, and £5 for subsequent offences.

Nets, snares, and decoy birds may be forfeited in the case of illegal taking of birds. Any person may demand the name and address of a person offending in shooting or trying to shoot any scheduled birds or taking scheduled birds' eggs.

Taking the list of protected birds in Kent. The close time in Kent is March 1st to August 13th. All birds are protected from being shot or snared on Sundays in nearly all the parishes of Kent. The commoner birds that a landowner, tenant, or persons authorised by either may shoot or trap without offence include :—House and tree sparrows, bullfinch, greenfinch, brown linnet, hawfinch, blackbird, missel and song thrushes, lark, hedge-sparrow, tree-creeper, the tits (except the long-tailed), wood-pigeon, stock-dove, dove, starling, rook, jay, jackdaw, sparrow hawk, &c.

The eggs of all the above-mentioned birds may be taken by anyone without offence, save those of the hawfinch, linnet, and lark, and in the metropolitan area the starling.

Of the commoner birds and their eggs that are protected in Kent may be mentioned the goldfinch, flycatchers, kestrel hawk, all the owls, swallow, house and sand martins and swift.

Of birds protected and the eggs of which are protected only in the metropolitan district :—wren, redstart, white throat, garden warbler, blackcap, nuthatch, cuckoo, wagtails.

Of birds protected, eggs not protected :—chaffinch, robin, lapwing, turtle dove. In the metropolitan district the magpie and its eggs are protected. In Kent there are certain areas in which all birds' eggs are protected.

In Worcestershire the protection of all birds on Sunday is not in force ; and somewhat fewer birds are protected.

I do not wish to criticise this attempt at protecting wild birds, but I would mention that to obtain the above brief information I had to study six brief Acts of Parliament. Why are they not summarised ? It took me several hours to summarise them, and then I had to consult the village policeman to know whether I understood them aright. He said he stopped all boys taking the eggs of any bird; gamekeepers kill everything they fancy, including owls and hawks, without interference ; he knew of several pole-traps at present in use in the district; he thought that farmers could shoot any bird they found doing harm to their crops, and that all persons might catch sparrows for Sparrow Clubs, though not directly authorised by a farmer. The latter is what one would expect, but the law states that no person other than a landowner or occupier of land, unless authorised by either, may kill any bird. School children, I think, fancy they are prohibited taking any birds' eggs, whereas they are free to take those of sparrows, blackbirds, thrushes, greenfinches, bullfinches, wood pigeons, and, if they can get at them, rooks, and other eggs not scheduled, but for fear of the policeman they consider they are doing wrong to take any. The chief duty of the police, as regards birds, appears to be to stop bird catching (more particularly the goldfinch) on Sunday, yet bird catching is legal on Sunday in the next parish. With regard to the birds protected, I have but little fault to find, and would only suggest that I think the chaffinch and hawfinch need no protection throughout the country, nor the eggs of the starling in the Metropolitan district.

Is it justifiable to decrease the number of injurious birds ? Unmistakably many of the smaller birds are increasing inordinately, to the detriment of cultivated crops, gardens, &c.

Weeds, injurious insects, and fruit-eating birds all entail increased labour to arrive at a successful crop, is it less justifiable to regulate the number of birds than the weeds and insects ? There is no doubt that man, whom Providence has placed as lord over the brute creation, was intended to control and regulate

the limits of animal and vegetable life. What would happen if rats, mice, rabbits, cats and wasps were allowed to multiply without check?

It is really our duty to regulate the birds in reference to the benefit of agriculture, horticulture and forestry, by specially preserving the most useful, and by lessening the number, in the most merciful way practicable, of those which are injurious.

What is the effect of lessening the number of small birds, and does it influence the number of insects? On the Continent they eat thrushes, blackbirds, house sparrows, and even robins.

In France and Belgium there are few small birds because they are shot and eaten, but in a tour of northern France and Belgium Mr. Frederick Smith says he did not see any crop damaged by insect pests, except the small ermine-moth caterpillars on apple trees, and birds will not eat these in any case. Here buzzards, harriers, the smaller hawks and owls and magpies are plentiful. But the crops were certainly not suffering from insect pests, and he thinks we very much overrate the good the birds do and do not take into consideration the harm they do in destroying the predatory insects, such as the lady-birds and their larvæ, the lacewing fly and ichneumon fly, all of which destroy our insect foes. Again, in the case of weed-seed eaten by birds, not all is cracked and digested, many seeds must be carried about and the weeds spread.

I propose now to speak of the food and habits of the commoner birds which have an influence for good or ill on our fruit plantations, commencing with those which are injurious.

Birds Partially Injurious to Fruit Cultivation.

The Common or House Sparrow, though not individually as destructive to buds as the bullfinch, yet by its immense numbers is a most serious pest to the fruit-grower, as it is to the corn-farmer, to the owner of poultry, by taking corn given to fowls, and to the gardener, by destroying his seedlings. This year, even in the beginning of November, it had started eating the buds of red currants, the injury being noticed by a grower, who was cottoning his bushes in order to try and protect them. The sparrow is very severe on gooseberry buds, particularly in February, and this injury is quite apart from insect attack, as Professor F. V. Theobald tells us no insect attacks gooseberry or cherry buds. It also eats plum buds, particularly those of the damson.

Mr. W. Huxley wrote me from Gloucestershire:—

"The sparrow is a great offender to most fruit growers, especially in winter and very early spring. I have known sparrows to destroy two acres of gooseberry bushes (in one year) by taking out 90 per cent. of the buds. The result was that the few buds that were left went to wood, and in a few years the bushes had scarcely a bud upon any of the lower branches. I have known sparrows do this to the following kinds of gooseberries: — 'Keepsake,' 'Crown Bobs,' 'Lancaster Lads,' 'Monarchs,' and 'Whinham's Industry.' On the other hand, I have seen sparrows destroy thousands of caterpillars of the winter moths. But as the destruction of winter moths does not depend upon the sparrow, I think it would be wise to destroy a good percentage of sparrows."

In May, or as soon as the gooseberry flowers open, the sparrows come to the blossoms and squeeze them, apparently for the sweetness of the nectar in the bloom, as they do not eat the flowers, but let them drop, and they continue to interfere with the blooms till the young gooseberries are formed; but this snibbing of the bloom causes the young fruit to cease growth, and invariably drop off. This gooseberry flower destruction is also practised by the chaffinch. Aspect of land does not appear to affect the matter, but the injury is worst near buildings and high trees. Mr. J. Blundell, a fruit-grower of long experience at Halstead, Kent, considers that the picking of flowers and young fruit of gooseberries is a habit acquired within the last few years, and that "Whitesmith," a two-thorned variety, suffers considerably, whilst "Warrington," which has three thorns, is not so much affected.

The sparrow pecks the blooms of plums, cherries, and sometimes of apples, and takes a few ripe strawberries, cherries, gooseberries, unripe red currants, also filbert and cob nuts.

Mr. J. H. Gurney and Colonel C. Russell in their excellent little book on "The House Sparrow," based on the careful examination of nearly 1,000 house sparrows at different times of the year, through 15 years, summarize the food of an adult sparrow as follows:—Corn, 75 per cent.; weeds of seeds, 10 per cent.; green peas, 4 per cent.; beetles, 3 per cent.; caterpillars, 2 per cent.; insects which fly, 1 per cent.; other things, 5 per cent. In young sparrows not more than 40 per cent. is corn, while about 40 per cent. consists of caterpillars, and 10 per cent. of small beetles. To see what a sparrow has been eating it should be killed in the afternoon; if caught in the evening, its food has in great measure been digested. Mr.

Gurney writes, "I am sure that while very young their diet is as much unripe corn and vegetable matter as caterpillars; even at the age of one day a sparrow will feed its young one on a grain of ripe corn." In this little book the customary and occasional food of both the adult and young sparrow is given for each month in the year.

Sparrows take the nests built by martins and swallows, and the general opinion is that the latter useful insectivorous birds, through being thus ousted, are less numerous than, say, 20 years ago. I was told of a case in which there were 16 martins' nests on a house, and when the owner returned he found them all occupied by sparrows. It has been stated that it is owing to the decrease of swallows that the hop aphis and wheat-midge are increasing so much.

The audacious sparrow, even in the few insects it does eat, takes this food from more useful birds. The sparrow multiplies fast, as it lays five or six eggs and has three or four broods in a year. One pair frequently produces more than 20 young in a season, and, were no disasters to betide them, the progeny of one single pair in six years would amount to millions. The Rev. H. H. Slater, in the excellent paper on "Wild Birds of the Farm," read before the Farmers' Club in 1905, says, that if the parent birds of a nest are killed, other sparrows will feed their young. The house sparrow is unmolested in towns, parks, and villages, and consequently, increases out of proportion to other birds.

Mr. F. Smith, in his very observant and practical paper on "The Fruit Grower and the Birds," read this year before the Maidstone Farmers' Club, adds to the already long list of sins of the sparrow, that he has seen it eating ladybird larvæ and beetles on hops, which insects are so useful in eating aphides. Among the injurious insects that the sparrow has been observed to eat are the looper caterpillars of the winter moth, aphides on damson trees and brussels sprouts, and beans, the leaf-roller caterpillar on roses, cabbage butterflies and their green caterpillars, caterpillars on gooseberry bushes, wireworms, crane flies, weevils on peas and beans. But, in general, although the insects may be very numerous, they constitute only a very small proportion of the sparrow's food, nothing appreciable to the damage done by the sparrow.

In America it is considered "a destructive bird, worthless as an insect killer."

The late Miss E. Ormerod, one of the kindest and wisest of naturalists in the leaflet "The House Sparrow," issued by her and the great bird authority Mr. W. B. Tegetmier, concludes by recommending the formation of Sparrow Clubs.

The Board of Agriculture has issued a useful leaflet with suggestions on the formation of sparrow clubs; some clubs, in fruit districts, include the destruction of the bullfinch, whilst in hop districts the greenfinch is included. Our forefathers knew that the sparrow needed to be kept in check when, at the beginning of last century, the churchwardens paid for sparrows' heads and eggs. We have made a mistake in destroying the sparrowhawk, and not taking practical interest in forming village sparrow clubs.

I have not mentioned poisoned wheat, but if sparrows increase, as at present, legislation may consider it wise to authorise the destruction of the sparrow by this means; perhaps appointing certain men thus to lessen the number, and collect and destroy the poisoned birds. Sparrows are poisoned in New Zealand and Australia (*vide* Mr. Charles Whitehead's article on "the Sparrow" in "Ornithology in Relation to Agriculture and Horticulture").

Mr. F. Smith says:—

"For reducing the number of sparrows the best thing he has known was Harding's prepared wheat. It would not kill anything larger than a sparrow or mouse—it would not kill rats or poultry. But the Government of the day brought in a Bill making it illegal to poison wheat in any way. Still, something might be done by appointing a certain number of men to kill sparrows by this means by permission of the Board of Agriculture."

The Bullfinch—which has been briefly described as not having one redeeming feature save his appearance, seems to be somewhat local, and is probably most plentiful near woods. Where numerous in a fruit-growing district, it seems that for self-protection they must be killed, as the damage they do to the buds is a very serious matter, and often they wantonly destroy the buds without even eating them. They commence soon after Christmas, when the first spell of frost has sweetened and swollen the buds, and continue eating them until the buds expand into leaves. The worst time is the beginning of March.

The bullfinch feeds on buds, especially of plants that bear fruit, such as plums, damsons, cherries, gooseberries, currants, apples, and pears; it shows a special liking for Greengage, Black diamond, Purple gage, and Early Rivers plums, which it will first attack in an orchard. It shows a preference for

certain varieties of gooseberries, and amongst apples, the buds of "Councellor" are favourites. It also attacks the buds of hawthorn, blackthorn, bird-cherry, larch, and beech. Mr. F. Smith, of Loddington, says that bullfinches rove about, in families of five or six, through the winter. A family will come into a fruit tree, and stay there till they have destroyed all the buds, both fruit and wood; they usually begin with "May duke" cherries, in the early autumn, and keep on with plums, gooseberries, currants, and medlars; ending, in late spring, with black currants and apples. For six months they live almost entirely on fruit buds; on dissection, their crop may be found full of buds, while insects occur in very small numbers. The crops of bullfinches have been found full of gooseberry buds. even during the time gooseberries were coming into blossom; for the other six months they feed on various weed seeds, as nettle, dock, chickweed, thistle, ragwort, plaintain, sowthistle, and the flowers of groundsel; but it is an open question to what extent this is of real value, as many seeds of weeds pass through birds undigested, and these seeds are distributed by the birds.

Mr. C. F. Archibald considers it is even doubtful whether insects form the main support of the young of the bullfinch, for they appear to be fed on seeds softened by their parents. When raspberries are ripe, bullfinches eat these; also blackberries, hips-and-haws, privet and rowan berries. As it commonly builds its nest in thick woods, protected by game preservers, it multiplies in safety; this accounts for its comparative abundance, and even increase, in the face of persecution.

Mr. George Abbey, in his articles on "British Birds" in the "Journal of Horticulture" for 1904, recommends lime wash spraying for the bushes, for preserving the buds, as most effective; and I can also recommend it.

The Blackbird, as far as the fruit-grower is concerned, is the blackest of thieves; this handsome but sly bird appropriates strawberries, currants, cherries, gooseberries, raspberries, apples, plums, and other fruit; they frequently commence the attack whilst the fruit is green, and if unmolested, they will in many cases, devour the entire crop. It is, unfortunately, almost impossible to keep them from the fruit with any degree of efficiency without destroying them; for they exhibit considerable cunning in finding their way under netting, and soon learn to disregard any method of scaring, which they find by experience may be braved with impunity.

Prof. F. V. Theobald wrote me recently:—"Blackbirds have been terribly destructive to fruit in Worcestershire, Herefordshire, and Kent this dry year; there are far too many."

This summarizes what I have heard from many growers. My brother wrote me from Pershore, Worcestershire:—

"Here the blackbirds have been an awful nuisance with red currants, raspberries, and gooseberries. This has been the worst year for birds I can remember; probably because there was so little fruit about, and the summer so dry. Next spring I intend to destroy all the young blackbirds in their numerous nests in my hedge-rows."

A fruit-grower in Bedfordshire wrote that in order to keep blackbirds and thrushes within reasonable bounds he has this year used 27 traps and caught 500 of these birds; first placing them on the strawberry beds, then under gooseberry bushes (where he caught most), and then under the apple trees.

Blackbirds appear to have increased largely lately, only a partial migration to the south takes place in the autumn with this bird; some authorities say that individuals reared in Britain do not migrate; but annually great flocks arrive on the eastern shores of England from more northern countries, remaining for a few days only and then proceeding southward. Blackbirds multiply fast, having two, three, or four broods in a season, the young of the first brood sometimes assisting their parents in feeding the young of the second. The food of the blackbird, other than cultivated fruit, consists largely of worms, beetles, caterpillars, and larvæ of insects; snails are eaten in winter, and probably slugs, also blackberries and the berries of hawthorn, yew, and dogwood. In nursery rhyme days they appear to have been a royal dish. Why not kill and export blackbirds to France?

The Starling, though an excellent bird on grass land and valuable in woods, is very severe and persistent on fruit, especially cherries and damsons, and, as the men say, "will not take no for an answer," and often will not leave the tree unless actually shot. Together with blackbirds and thrushes it attacks strawberries. Mr. George Abbey informs me that at Eltham it destroyed also pears, apples, and plums. They swoop down in flocks on the raspberry fields at Swanley, in Kent, especially in hot weather.

Starlings are said on all sides to have greatly increased; they also come from

abroad. Their numbers should be kept within bounds, as, with the rook, in moderate numbers they are farmers' friends, yet if allowed to increase unduly they become equally Injurious. Their food, other than fruit, consists chiefly of wireworms and leather jackets, wood lice, millipedes, worms, snails, slugs, ground insects, and their larvæ. Mr. W. H. Neild informs me it eats the looper caterpillar of the winter moth. It takes ticks from the backs of sheep, and thus informs us that the sheep need washing. The starling is the most widely distributed of our birds, and is numerous in cultivated districts. It lays four to seven eggs, and rears two broods yearly. It appears to be acqulring an increased taste for fruit.

The Missel Thrush, which is larger than the song thrush, differs somewhat in the size and shape of spots on the breast, is less common than the song thrush, but more severe on fruit; it is a resident of Britain, and is an example of a species of bird whose distribution has become more general within comparatively recent times, as there is said to be good evidence to prove that a century ago it was either absent or very rare in many districts, particularly towards the north; it makes its nest early in the year, sometimes before the leaves are out on the trees, lays generally four, rarely five, eggs, and has two or three broods in a season, so has good opportunity to multiply. In Kent it is considered one of the worst birds with fruit, specially troublesome with cherries and soft fruit; it persistently eats pears, apples, plums, damsons, and many kinds of berries; it is fond of black currants, which most birds avoid. Its food, other than fruit, Mr. W. Swaysland, in "Familiar Wild Birds," tells us, consists of berries of mountain ash, service tree, yew, juniper, holly, ivy, hips, haws, grain, seeds of various kinds, caterpillars, beetles and other insects, worms, slugs, and snails. Aristotle mentions its fondness for mistletoe, it being almost the only bird that touches it.

Gilbert White tells us it is the largest bird of all the feathered tribe that has music in its voice; it is comparatively tame in nesting time, but most shy and wild in autumn and winter: it is one of those birds that appear to pair for life, and even when later in the year they gather in small flocks, like starlings, to attack a crop, husband and wife may be seen in close company.

Missel thrushes are good food, which is one compensation for the disagreeable task of killing them.

The Song Thrush, though resident and plentiful throughout the British Isles, is, to a great extent, a migrant, and this fact accounts for its persistent presence in gardens and orchards, when the fruit is ripe; even after large numbers have been killed, fresh arrivals take the place of the slaughtered birds; the same applies to the blackbird, though it is not perhaps so essentially a migrant as the thrush. Professor Alfred Newton tells us, that nearly all the young thrushes reared in this country, emigrate as soon as they are fit to journey, and a little later are followed by most of their parents; so that many parts of the kingdom are almost bereft of this species, from October to the end of January; whilst in other parts, examples can always be found, a considerable immigration takes place in the autumn on our east coast, by birds coming from Northern Europe; however, in most localities these newcomers depart, after a short sojourn, and are accompanied by many of the home-bred birds. The arrival of the birds in Belgium, France, and Germany is marked, by thrush shooting beginning on the 12th of August.

On the continent of Europe, the autumnal influx of the birds, bred in the North, is regarded with much interest, for they are easily ensnared, and justly esteemed for the table, while their numbers make their appearance in certain districts a matter of great importance.

Professor F. V. Theobald says the thrush is far more helpful than the blackbird; for nine months it feeds solely on snails, worms, slugs, insects and berries, only when the fruit is ripe does it become in any way a nuisance. The thrush continues its snail eating all through the summer, which the blackbird does not. Thrushes eat leather jackets in spring on clayey land; they lay four or five eggs and rear two or three broods in a season. Gilbert White mentions thrushes eating the root of Cuckoo pint in severe weather, the root being warm and pungent. The thrush family, which includes the blackbird, song, and missel thrushes, fieldfare and redwing, are reduced in numbers, through starvation, by a long and severe winter; it is twenty years or more since we have had a winter that has affected the birds severely.

The Chaffinch.—On this bird the judgement from Mr. W. E. Collinge has fallen, after due study of its habits, that, whilst not favouring ruthless destruction, it should not be protected at all.

A flock of these birds causes astonishning

harm to newly sown seed and sprouting crops, particularly to those of the cabbage, turnip and radish family, and lettuce. It is, in company with the house sparrow, a great disbudder of gooseberries, currants and plums. Mr. F. Smith says they are especially destructive after frost, when these birds will be found in twos and threes all over the plantation, eating the buds; they squeeze the blossoms of plums, cherries, gooseberries and currants, to extract the honey in them; they are also very fond of ladybirds and their larvæ, which are so beneficial in destroying green fly or aphis. Though it eats corn, it is only when its numbers are very great that it causes any serious loss to the farmer. It eats beech nuts and beech-seedlings, seeds of Scotch pine and other conifers and quantities of weed seed. It also feeds largely on insects, and brings up its young almost entirely on an insect diet; it eats caterpillars, frequently those on apple trees, and American blight or woolly aphis, also aphides on cherry, plum, damson, apple and chrysanthemum. It lays four or five eggs, and has generally two broods yearly, it is considered to be partially migratory, coming from the North in large quantities in the end of October or beginning of November.

The Greenfinch, or green linnet, is a resident, and is abundant throughout Britain, being found at all seasons of the year, particularly in cultivated or wooded districts. It appears to feed in the fields in summer, and around the farm buildings in winter. This strongly built and noisy bird needs, like the chaffinch, no protection; if anything, it is more destructive, and for a longer period. The adult birds, like the sparrow, eat but few insects; they are sometimes very destructive to sprouting crops. A field at Halstead, Kent, sowed with milled sainfoin had to be ploughed up owing to flocks of greenfinches taking all the seed. It eats grain and large quantities of weed seeds, of which it also probably distributes many. Mr. L. H. Page, of Sittingbourne, says it eats the seeds on strawberries when ripe. It does not eat fruit, but accompanies the sparrow destroying buds; it also picks some blooms to pieces. It is terribly destructive in pulling hop flowers to pieces to get at the seeds, and comes in large flocks and litters the ground with the flower bracts of the hop. It lays four to nine eggs, and has often two broods a year. Its young are chiefly fed on insects and a few soft seeds. Professor Theobald says that small winter moth larvæ and caterpillars of various injurious tortrices are fed to the young. Mr. C. F. Archibald, in his excellent articles on "Wild Birds of the Farm," in the Royal Agricultural Society's Journal, from which I have quoted with his permission in other parts of this paper, remarks, in connection with the greenfinch, that an undue increase of small birds is the inevitable result of exterminating such of their natural enemies as the sparrow-hawk, jay, and magpie.

The Hawfinch is larger than the other finches and has a notably powerful bill. It is considered to be increasing in numbers. It is sly in its habits and seldom affords opportunity for observation. It feeds on the seeds of trees, is very fond of green peas, and sometimes pecks apples and pears to get at the pips; it eats nuts and is said to be fond of damsons. In summer it captures quantities of insects, principally for its young. Mr. Archibald writes that a female hawfinch was found to contain forty caterpillars. In some localities this bird is found to be in excess.

Larks are complained of at Wrotham, Kent, as pecking early strawberries and being difficult to scare.

On light soil they eat young peas and vetches when just coming through the ground, and in cold weather come in flocks and destroy fields of cabbage and other greenstuff. The question may be asked whether the good they do in eleven months balances the harm they do in one month.

The Rook.—This bird, capable of great good and great harm, commences eating strawberries when green before one has to scare for other birds; it eats cherries, gooseberries especially in dry weather, and sometimes apples and pears; it dearly loves walnuts, also cob and filbert nuts. In the raspberry growing district at Blairgowrie in Scotland, the rook is found to be a very serious depredator, though in the Swanley district, Kent, even close to a rookery, the raspberries were not attacked. In order to keep the number of rooks under control the newly-fledged birds in a rookery should be shot, say two out of each nest, in order to make the number stationary and not increasing.

The food of rooks includes wireworms, leather jackets, slugs, snails, worms, woodlice, millipedes, and caterpillars of the Winter Turnip and other moths. Mr. W. Wood, of Crockenhill, told me that years ago, before the days of grease banding and spraying, one year, when orchards were as bare of leaf at midsummer as in winter, the winter moth caterpillar having defoliated the trees, rooks once came in large

numbers and fed plentifully on them, but he has never seen this before or since. Mr. A. Thomas of Sittingbourne mentions the rook as eating the caterpillars of the Lackey moth. On a farm, rooks are often very troublesome in disturbing and eating corn, maize, and peas, also on newly-planted and mature potatoes.

Henry VIII. dealt with the damage done by rooks to corn and grain at seedtime and harvest, and enacted "that everyone should do his best to destroy rooks, crows, and choughs, upon pain of amercement, and that every hamlet should provide and maintain crow nets for ten years, and that the taker of the crows should have after the rate of 2d. per dozen" (about equal to a present value of 4d. per crow).

The Jackdaw does little injury to fruit, is partial to cherries, destroys many insects including wire worms.

The Magpie eats cherries, but is rare; valuable in destroying the wood pigeon.

The Jay, where a fruit plantation is near a wood, is apt to peck and disfigure apples; it takes nuts, is fond of green peas and plums, and is said to feed on ripe cherries. It eats the eggs of the blackbird and wood-pigeon, and is useful in this way. Its food consists of acorns, beech-nuts, worms, snails, slugs, cockchafers, beetles, insect larvæ, mice, eggs and young birds. This beautiful and sprightly bird is becoming rare, owing to its persecution by the game-keeper.

The Wood Pigeon and *Stock Dove* are no friends to the farmers, and are seriously increasing in numbers in some districts, as besides our native species, immense flights arrive on the east coast from the continent, during the winter. Professor Theobald says these, although smaller, do the most harm. The close preservation of wood harbours the wood pigeon, which feeds on beech mast, acorns, grain, vetches, peas, young shoots of turnip tops, white clover, and occasionally garden crops, including beet and lettuce; in the woods it eats the seeds, buds, catkins of trees, and by its weight breaks the leaders of Douglas fir, silver fir and spruce. Its food is entirely vegetable, it does not assist in the destruction of insects. These wary birds will eat a whole field of cabbage in winter; they eat cherries from green to ripe, and I had a complaint from Pershore that this year the wood pigeons, or coifs as they call them there, were a plague and took the gooseberries whole. This bird should be decreased in numbers, it is good food and worth 1s. per brace. One fruit grower near Maidstone described the bird "Bad, except in a pie."

BIRDS RATHER OR DECIDEDLY USEFUL.

The Tits.—Of these beautiful and restless little birds we have six species, all resident in Britain, as they feed mainly on insect life; they are among the most useful of our small birds in the orchard; the mischief they do is comparatively small. The tits are very prolific, laying nine or ten eggs to a sitting, and have two broods in a year; they remain in company sometimes after they can fly.

The Blue Titmouse is a cheery little bird, and the most common of its tribe; it does sometimes serious damage by pecking cherries, and the sweeter flavoured apples and pears. Professor Theobald says it does more good in the orchard than any other bird; in winter it hunts amongst the boughs and twigs for woolly aphis, apple blossom weevil, aphis eggs, thrips, moths and their eggs, larvæ and chrysalides; it eats the caterpillars of the gooseberry and currant moth, the grubs of wood-boring beetles, the maggots in the round galls on oak and apparently the caterpillars of the little green oak-moth; scale insects especially apple scale, also spiders. The blue tit pulls half expanded apple and pear blossoms to pieces, apparently searching for eggs or insects. Prof. Theobald tells us that in all cases when he observed the birds on currant, pear, and apple, the buds were invaded by phytopti.

Prof. A. Newton says titmice search for food in a band, the reason apparently being that their food is collected into particular spots often far apart, but where it does occur, occuring plentifully. Thus a single titmouse searching alone might hunt for a whole day without meeting with a sufficiency, while if a dozen are united by the same motive it is hardly possible for the place in which the food is lodged to escape their detection, and when found a few call notes from the lucky finder are enough to assemble the whole company to share the feast. At Evesham it is said that tits take the moths from the grease bands on the trees. They are mentioned as eating winter and codlin moths, and are believed to eat winter moth caterpillars.

The Great Tit, or Tomtit also harms pears and apples, by pecking them at the base near the stalk, but he is said to prefer sunflower seed to this, and I know two large fruit growers, who have grown sunflowers in their plantations with the object of alluring

them from the fruit, and I believe with success. Gilbert White mentions their fondness for sunflower seeds. In the case of the great tit, insects do not constitute the whole of its diet, for yew berries, the kernels of beech mast, and hazel nuts, and other vegetable food, come under notice. Like the blue tit, it sometimes eats bees during winter; it has a habit of pulling straws out of thatch in order to get insects; it does not disdain grain.

The Cole Tit inhabits pine plantations, but also comes to fruit plantations. Mr. F. Smith says it destroys black-currant buds when they are opening, he finds it worse than the blue tit at the pears and apples, but adds, that for several years he has saved his fruit in the garden, by planting sunflowers; if there is enough sunflower seed they will not touch fruit. He goes on to say in reference to the tits, that they frequently peck the bunches of pear and apple blossom buds, just before they open, and in all cases he has examined, they contained the larvæ of some insect; the tits eat the caterpillar and chrysalis of the Bud moth.

The Long-tailed Tit feeds almost entirely on "looper" caterpillars, beetles, scale and other small insects, of which it is able to obtain an abundant supply, even in winter. Mr. George Abbey says it consumes countless numbers of aphis eggs, and he has known it clear a plantation of black currants completely of black aphides.

The Robin Red-breast, this most familiar and favoured bird, is generally distributed throughout England. Its food consists principally of earthworms, small slugs, spiders, wood lice, beetles (including the grubs of the May bug), moths and butterflies, and caterpillars (including larvæ of the Swift moth), and, in the winter, chrysalides, fastened to the twigs of trees and their trunks, and to palings, and in the walls. It eats a few red currants and cherries, and in a glass-house will peck and eat grapes; of the wild berries it eats those of ivy, honeysuckle, spindlewood, and deadly nightshade. Young robins may be seen hunting for insects under gooseberry bushes and raspberries.

Professor Newton tells us, that although the robin is resident, its numbers are subject to very considerable variation, according to the season of the year. At no time do the robins collect in bands; but towards the end of summer they may be seen in the south of England successively passing onward, the travellers being mostly, if not wholly, young birds; and so the great majority disappear, departing it may be safely presumed for more southern countries, since a few weeks later the markets of most towns, first in France and then in Italy, are well supplied with this species.

The Hedge Sparrow, Accentor, or Shufflewing, belongs to a different family, though about the size of the house sparrow. It has a more slender and pointed beak like the robin, which it is similar to in its food. It is one of the commonest yet most valuable birds in the garden, field or wood. Its food consists of worms, insects in various stages, seeds of grass and other plants, and, in hard weather, of bread crumbs and scraps from houses; the young are fed largely on caterpillars. This amiable, unobtrusive, and harmless bird deserves protection and support. It is said to be fond of bullaces. I have no mention of other fruit that it eats.

The Redstart is a migratory bird, arriving in this country about the beginning of April. Its food is almost entirely insectivorous, and consists chiefly of ants and their eggs, flies, moths, spiders, caterpillars, worms, and beetles. It is never known to touch fruit; it builds its nest in orchards and about houses.

The Tree-creeper is an active little bird with a slender curved beak. Its curved claws and stiff pointed tail enable it to ascend the trunk and branches of trees with ease and rapidity as it searches for the spiders, caterpillars, beetles, and other insects hidden in the bark. It is most useful in orchards; it eats scale. In searching for food, it will begin at the bottom of a mossy wall and work upwards, or at the foot of a tree and work its way up in a spiral direction.

The Pied Wagtail.—This graceful bird is a resident, but subject to partial migration. It feeds almost entirely upon insects, and is frequently seen following the plough. Mr. W. H. Neild places aphis amongst its food. It is a friend to the farmer in eating the water snails that act as host to the liver fluke, so fatal to sheep. Nothing but good can be said of the plover, swallow, martin, and swift, but they do not, as a rule, directly affect fruit cultivation.

The Wren.—This active, fearless little bird, which braves the winter of the British Isles and daily sings its lively song, save in severest frost, is entirely blameless; its food consists of various insects, including aphides, woodlice, also small wild seeds, and it feeds its numerous family on green caterpillars from fruit trees.

The Golden Crested Wren devours scale insects readily.

The Nuthatch is a resident common in the woods of southern and central England; it is considered to be becoming rarer. Mr. O. V. Aplin attributes this to starlings turning them out of the holes in trees they have chosen for their nest. This bird feeds on insects, beech mast, acorns, and is very partial to hazel nuts; it also eats hard seeds. It has sharp claws, and runs up and down the trunks and branches of trees with equal facility. This is a most useful bird except perhaps in nut plantations.

The Common or Spotted Flycatcher is of all our summer visitors the most mute, and the most familiar; it also appears the last of any, arriving about the first week of May from its winter quarters in Africa. Its food consists of insects captured on the wing; sawflies are a favourite food, large moths (such as the yellow underwing), white butterflies, flies, beetles and aphides; in autumn, it sometimes eats berries. It is generally distributed about England during summer, and is one of the few species which nest in the London parks and gardens. It has been accused of eating cherries and raspberries, dissection, however, has proved that the attraction is not the fruit itself, but the living creatures which are to be found upon it. The services of the spotted flycatcher, in destroying swarms of insects, many of which either plague ourselves or injure our crops, are not marred by any mischievous propensities. The birds should therefore be encouraged, and their nests and eggs carefully protected.

The Warblers, which include the whitethroat, lesser whitethroat, blackcap, garden warbler, wood wren, willow wren, and chiffchaff, come to us in spring from the South of Europe and Africa; the males usually arriving some days before the females.

The Whitethroat or Nettlecreeper is perhaps the best known and most widely distributed, it feeds on a quantity of caterpillars, aphides, and other garden pests, but in July and August the birds bring their broods into gardens and orchards, and make havoc among the currants and raspberries; it also eats green peas and pecks green gooseberries.

The Blackcap is larger than the whitethroat; an occasional one will stay the winter. Mr. F. Smith says of it: "A family of blackcaps in a cherry orchard commit great havoc. They do not eat a quarter of the fruit they pick, they are also very fond of raspberries and figs. It is the worst summer bird we have in the fruit plantations, and I think the only one of our summer visitors that does much mischief.

The Garden Warbler confines his attacks on fruit, to late cherries, raspberries and currants; it is very fond of the caterpillars of the white cabbage butterfly.

Mr. C. F. Archibald writes of the smaller warblers (the wood and willow wren,) "if ever they touch fruit, it is certainly exceptional, and for practical purposes, it is safe to say, that the benefit derived from their presence is not the least detracted by any loss of garden produce."

The Cuckoo is a soft-billed insectivorous bird, which lays its egg, or places it, in the nest of other insect-feeding birds. Buffon says of it, where the cuckoo retreats to in winter is not known, to what country it retires, or whether it has ever been seen on its journey, are questions that we are wholly incapable of resolving. Its habits are described thus "In April, come, he will; in May, he sings all day; in June, he changes his tune; in July, away he will fly; in August go he must."

The cuckoo's food is largely caterpillars, hairy caterpillar like the Ermine moth and "woolly bear," avoided by other birds; also gooseberry caterpillars, apparently both of the magpie moth and sawfly, the latter, even ducks will not eat. Cuckoos are not so numerous as one might judge from the sound they make, and so they do not affect these pests much. It also eats flies, beetles, grasshoppers and snails, but its chief food is caterpillars. F. Norgate gives instances where destructive visitations of *Bombyx pini* and *Liparis chrysorrhea* have been checked by these birds.

The Wryneck, cuckoo's mate or leader, arrives a day or two before the cuckoo: its food is ants and their eggs, caterpillars and insects on bark; the bird appears to form a link between the woodpecker and cuckoo families; it is not numerous.

The Woodpeckers are useful in an orchard. They eat the Goat moth caterpillars which injure fruit trees, though chiefly eating insects in decayed wood. The green woodpecker, which is the commonest, eats ants and their eggs, the larvæ of the bark beetles, especially those of the elm bark beetle (*Scolytus destructor*). The great spotted woodpecker eats scale insects. The woodpeckers do not eat our cultivated fruits. The greater and lesser spotted woodpeckers feed chiefly on larvæ in decaying wood and on wild fruits and berries.

The Plover eats slugs and frequents the large strawberry fields in Herefordshire in autumn and winter, and is considered to feed on the small black slug which infests the strawberry plants; these enormous flocks of peewits are encouraged and never disturbed by the owners.

The Nightjar captures insects on the wing at dusk.

The hawks and owls need all the protection and encouragement possible from the fruit-grower.

The Kestrel Hawk is one of the most useful birds we have. By far the greater portion of its food consists of field mice and beetles, including the destructive cockchafer. It also eats young rats, moles, weasels, small birds, lizards, and frogs. It is only an occasional bird that interferes with game, but this is rare. Canon Tristram mentions that one of these birds contained 178 wireworms. Mr. George Smith, of Maidstone, writes:—

"What we want in the country is to get strong protection for our good old friend the kestrel, now, I am sorry to say, rapidly disappearing. I have observed him for sixty years, and rarely indeed has he been caught in any mischief; his food is mice and beetles, occasionally a lark or small bird. The same with regard to the barn owl most emphatically."

The Sparrow-hawk eats many injurious insects, including the destructive crane-fly. It destroys wood-pigeons and blackbirds, of which we have far too many, and is one of the most efficient means of keeping the number of small birds within bounds. Moreover, its presence is beneficial in scaring birds off ripening corn. W. Swaysland tells us it has been calculated that a sparrow-hawk destroys on an average about three birds per day, and this would give a total of over 2,000 birds annually for every pair of sparrow-hawks; unfortunately sparrow-hawks are somewhat liable to take game and poultry, but as a total are very useful birds.

The Barn Owl is a most valuable mouse killer, nine-tenths of its food appears to consist of mice; the number it catches is wonderful. In 1,124 pellets examined by Mr. L. E. Adams, remains of 2,397 mice and rats, and 97 sparrows were found.

The Tawny Owl as well as the short-eared and long-eared owls should be strictly preserved; its food consists largely of rats, mice, also water rats, young rabbits, squirrels, small birds, fish, whilst beetles, including the destructive cockchafer, are sometimes devoured by it in great numbers.

SUMMARY.

Mr. W. E. Collinge, the Honorary Secretary of the Association of Economic Biology, in his report for 1905, issues a *Summary.* He strongly advocates the most stringent measures for exterminating house sparrows, wood-pigeons, and stock-doves as being distinctly injurious. He is strongly in favour of permitting (indeed encouraging) the taking of the eggs of the chaffinch, greenfinch and bullfinch. The remaining species are, in his opinion, beneficial, provided they are not permitted to increase unduly. I would add in fruit-growing districts, besides reducing the numbers of the birds already named, it may be absolutely necessary to decrease the number of blackbirds, starlings, and, more reluctantly, of the missel and song thrushes, also of the rook in districts where it interferes with fruit. In the case of hawks (particularly the kestrel), and of owls (particularly the barn owl), swallows, flycatchers, wagtails, and all such birds, no effort should be spared to protect and encourage them, and every inducement offered to them to increase in number. It is the duty of those who own woods to check the undue increase of wood pigeons, and of those who own rookeries to shoot a proportion of the young rooks to keep the numbers stationary.

In conclusion I have to thank very heartily the gentlemen, nearly fifty in number, who have most kindly filled in the forms I sent out with their experience as to the food of birds, and their influence on insects injurious to fruit. One thing these answers prove is that many fruit growers and farmers are keen observers of the habits of birds, and do not kill birds without good reason.

DISCUSSION.

Mr. H. E. DRESSER, F.Z.S., F.L.S., speaking as a fruit grower and a naturalist, said in his experience the rook did not do any harm in orchards except to walnut trees. The titmouses did comparatively little harm, except in the way of picking the base of apples and pears, but the wasps started where they left off, and created the great damage which ensued. On the whole he thought the titmouse did far more good than harm. The best destroyers of wasps were the honeybuzzards, which were almost extinct in England.

Mr. BUNYARD stated that, having been bred and born in the fruit industry, and being connected with a very large fruit-growing firm, his experience was

that the balance was by far in favour of the bird. He was sorry to say, however, that he had to place the bullfinch on the black list. During the last two or three years he had carefully dissected the crops and stomachs of some 50 or 60 bullfinches, and he found in nearly every case the contents consisted entirely of buds of fruit trees, more especially of the gooseberry. With regard to tits, he bore out what the last speaker had said—tits did attack apples and pears, and, unfortunately, they did not confine themselves to one particular fruit. He had known cases where the tits had attacked every pear on a tree, by pecking a little out of the top of the pear, and the wasps immediately took advantage of that, with the result that the pear became practically useless. That, he thought, was about the only case in which fruit growers could fall out with tits. There was no doubt that the warblers were nearly all insectivorous. The author had made a remark in regard to the cuckoo using its instinct to choose the nest of an insectivorous bird for depositing its egg, but that was not always the case. He had found eggs of the cuckoo in the nests of the greenfinch, bullfinch, and linnet, and he knew of a case quite recently where it was not only found in the hawfinch but also in the nest of a great tit. He thought that was a record, but perhaps the explanation of it was that the egg was placed in the nest of a great tit which had built its nest in a nesting-box. Very little could be said against the chaffinch. There was no doubt that all the birds Mr. Hooper had mentioned did an enormous amount of harm. He was quite convinced that the sparrow, during the time it had a brood of young, ate very little vegetable food. He had examined the stomachs of sparrows during that time, and quite failed to find anything in the way of vegetable matter, and therefore he thought it must be admitted that a great many of these birds did as much good as they did harm. Owing to the Wild Birds Protection Act a great many wild birds had increased largely, and consequently had become pests. Therefore he must say openly and without prejudice, though he was a great lover of birds, that he considered the sparrow, the starling, and the bullfinch, and some of the gulls, should certainly be taken off the Wild Birds Protection Act list.

Mr. ERNEST BELL felt a good deal of sympathy with Mr. Hooper in his difficulty in understanding the law with regard to birds. He recommended him not to take a policeman into his confidence, because it always resulted in confusion worse confounded. In his opinion the paper had been misnamed; it ought to have been called "Fruit Growing and the Unprotected Birds," instead of "Fruit Growing and Bird Protection," because not a single bird the author had mentioned was protected, or ever had been protected, by English law. He had received a letter from Mr. Meade-Waldo, of Hever, Kent, saying that he could not attend the meeting, and trusted that someone who understood bird protection, with relation to fruit culture, would be able to do so, and point out that no single bird, injurious to either fruit culture or agriculture was, or ever had been, protected by any law, and that the cause of the undue increase in blackbirds, thrushes &c., was due primarily to an absolute immunity from hard winters for eleven years, to the great reduction especially in the number of jays and other more or less predatory birds, and game preserving generally; also in the neighbourhood of towns to the large extent of villa gardens which were now growing up and affording abundant covert, and, in many cases, protection. It seemed impossible to knock into the heads of fruit growers the fact that the injurious birds were not protected. He had been that afternoon to the office of the Birds Protection Society, to find out exactly what the letter meant, and had ascertained that none of the birds which were accused of being injurious were protected by the law. He had with him a schedule of the protected birds, and it did not contain a single instance of a bird which had been mentioned that evening as injurious to fruit culture. Though they were not protected by law, there was a provision which allowed Boroughs and County Councils to give them a certain amount of protection. The only place in which the blackbird had been partially protected was in the Orkney Islands; the thrush was partially protected in two counties, but the starling and sparrow were not protected at all. The County Council protection was very partial, because even when the birds were on the list, the owner of the property had the right to kill them or take their eggs at any time. If fruit growers found they were injurious to fruit trees, they were at perfect liberty to kill them. What was really required was not less bird protection but more bird protection, especially of the sparrow hawk, the kestrel, the jay, and birds of that description, which tended to keep down the numbers of injurious birds when they increased too much. He had made his remarks because there was a general feeling that birds were protected too much in England, and it would be a great pity if that opinion went abroad, because the law was a most moderate one, and did not protect any birds against which fruit growers had a particular spite. He readily admitted that some birds were injurious to fruit growers, but cautioned them against indiscriminate destruction, because in countries on the Continent, where the extermination of birds had been attempted, it had been found that the plague of insects was very much more injurious to crops than the plague of birds ever had been, or was likely to be.

The CHAIRMAN desired to correct the remarks Mr. Bell had made with regard to the Act for the Protection of Wild Birds. It was quite a mistake to suppose that any birds were unprotected. He had gone very carefully into the question, because he was a member of the Departmental Committee appointed in connection with fruit culture; and Mr. Clarke, the legal adviser to the Board of Agriculture, gave a very clear exposition to the Committee of the Acts of Parliament dealing with wild bird protection. Those who were

interested in the matter should read the minutes of Mr. Clarke's evidence. The Act said that "Any person who between the first day of March and the last day of August shall knowingly and wilfully shoot or attempt to shoot, or shall use any line, trap, snare, net, or other instrument for the purpose of taking any wild bird, or shall expose for sale any wild bird included in the annexed schedule, shall forfeit £1 for a first offence, and in the case of any other wild bird (which included everything which was not scheduled) shall, for the first offence, be reprimanded, and discharged on payment of costs, and for every subsequent offence forfeit and pay for every such wild bird (in respect of which an offence is committed), a sum of money not exceeding 5s. in addition to the costs." That protected certain birds absolutely, and other birds partially. There was a saving clause at the end of the section saying, "This section shall not apply to the owner or occupier of any land, or to any person authorised by the owner or occupier of any land, killing or taking any wild bird on such land, not included in the schedule." It would, therefore, be seen that the unscheduled birds were protected from the public, but were not protected from the land occupier. He also desired to point out that the County Councils, whose duty it was to publish notices under the Act, had the power to modify the schedule, and if they did so they were under obligation to notify the fact in the county. Some of the County Councils gave those notifications in a manner most deleterious to the interests of fruit growers. They quoted the words of the Act, saying that all birds were protected under a penalty, and there they stopped, and did not go on to quote that the Act did not apply to the owner or occupier of the land. The chief objection to such a notice, was that the land owner thought he had no right whatever to kill the birds, and that the Act was unjust towards him. The result would be that, sooner or later, there would be a very great outcry against the Acts; whereas, if they were properly interpreted and acted upon, they would be perfectly fair both to the land occupier and to those who desired to protect useful and interesting birds.

Mr. BUNYARD said that, from his experience of fruit growers, they did not hesitate for one moment to shoot birds which were doing them harm. He believed Mr. Hooper sent a query to the *Horticultural Journal* not long ago as to the food of the blackbird. It was well known that the thrush ate snails in large quantities, but it was a moot point whether the blackbirds did. Having seen the query in the *Zoologist*, and being struck with the fact that very few people could answer the question straight off, he made inquiries among his horticultural friends, and not one of them could tell him they had seen a blackbird eating a snail. He spent his last summer holidays at a farmhouse in Kent, and, on looking out of the bedroom window one morning, he saw a blackbird on the path which he believed was eating a snail. On looking at it through his glasses his surmise was confirmed, and on going out into the garden he found the partly devoured snail lying on the path. While that was very good evidence, he did not think it could be generally said from one isolated case that blackbirds ate snails. He belived the blackbird was eating a snail in that instance because the summer was a particularly dry one, and it ate the snail for moisture. He was strengthened in that opinion, because he found the blackbirds were eating the apples in the orchards which had fallen to the ground, and had also attacked apples still hanging on the trees, which was a rather unusual thing for blackbirds to do.

Mr. MATTHEWS (Secretary, Central Chamber of Agriculture) thought that only one conclusion could be come to from the tenour of the present and many previous discussions on the bird question, namely, that there were very few people in this country who knew anything at all accurately as to what the food of birds was, and whether the good they did overbalanced the harm, or vice versa. Dr. Hollrung, of Halle, had for the last ten years been carrying out some very exhaustive experiments on the food of rooks, and during that period had carefully examined over 4,000 specimens, arriving at the conclusion that good and evil done by rooks about balanced each other. He thought it would be found that the same remark applied to many other species of birds. He was delighted to hear the Chairman's statement that he had no sympathy with those who desired to kill off all classes of birds, and he was still further relieved to hear the very open-minded remarks made by the author of the paper. It brought him back to the point from which he started, viz., that it was very necessary that an exhaustive scientific inquiry should be carried out. On one occasion he proposed that the Board ef Agriculture, or the Board of Agriture and the Home Office jointly, should appoint a scientific committee for the purpose, and those interested in the question would not be satisfied until that was done. With regard to the bullfinch, he was afraid that, superficially, a good deal of evidence could be produced against that bird. There was evidence that he destroyed many fruit buds, but there was further evidence that at certain seasons it ate a large quantity of weed seeds. Mr. Hooper had said he doubted whether this did material good, because the seeds were carried away by the birds without being digested and dropped in other places. That was a very unfair bias against the bullfinch. If that bird preferred undeveloped fruit buds, it might be assumed he would also prefer undeveloped weed seeds; and, speaking in general knowledge of the bullfinch, he knew that that was the case, particularly in the case of groundsel. The bullfinch always preferred the head of a groundsel which was only just shooting out to one that was fully developed. It was not his experience that the County Council

orders had a tendency to check the destruction of birds and the stoppage of bird nesting by school children. From personal knowledge and observation he estimated that the orders had not saved ten per cent. of the birds which children used to destroy. Birds nesting was his favourite hobby, and when he was hunting about for bird nests he still found as many nests destroyed and broken eggs lying beside the road as he used to many years ago. A paper written by Mr. Smith had been quoted a good many times in the paper, and, in referring to the starling, Mr. Smith stated that he did not think it had altered its food. If Mr. Smith made such a statement in regard to a bird which was common in every district in England, it must detract a great deal from the force of his other remarks, because he (Mr. Matthews) knew that the food and the habits of the starling had altered very considerably during the last ten or fifteen years. Mr. Aplin was the first man in this country to call attention to the fact nearly ten years ago. He therefore thought too much attention must not be paid to what Mr. Smith had said with regard to certain other species.

Captain TAILBY thought there was one point in the admirable lecture which Mr. Hooper had given from which nobody would dissent, namely the protest which had been made against the destruction of the natural enemies of many of the birds mentioned, namely, the kestrels and the owls. The harm done to game by kestrels and owls was mainly imaginary. All fruit growers agreed that kestrels and owls deserved protection. His main reason for speaking was to endeavour to get help in seeing that the Pole-trap Act was put in force. The author had read a letter in which it was stated that the correspondent knew of the existence in Kent of pole-traps at the present moment. It was the duty of the local policeman to know the law of England, which was that pole-traps were absolutely prohibited, and if he was not cognisant of the existence of such a law the sooner he was removed from his duty the better. It was lamentable that owls, which did nothing but good, should be allowed to be destroyed owing to the ignorance of local policemen. He desired to state publicly that Mr. Lemon, the Secretary of the Society for the Protection of Wild Birds, would, if he was informed of the existence of pole-traps in any particular locality undertake a prosecution. He (Capt. Tailby) would personally guarantee that this would be done.

Mr. P. F. BUNYARD replied that he knew of one place where a pole-trap was still used, but it was a modification of the pole-trap, and difficulty might be experienced in prosecuting the offender for that

Mr. J. HERDMAN desired to make a few remarks in reply to the criticisms which had been passed on the bullfinch. He knew of an apple tree in South Wilts which, in one particular year, was covered with bloom, and, at the same time, was swarming with bullfinches. The owner of the garden was a great advocate of the protection of birds, but some of his neighbours, who were energetic farmers, did not entertain quite the same opinions, and suggested that the bullfinches should be killed otherwise there would be no apples. He declined to have the bullfinches interfered with. The ground under the apple tree was strewn with buds, but the tree yielded a finer crop of apples that year than it had ever done before, the obvious inference being that the buds, which were admittedly destroyed by the bullfinches, were unhealthy buds harbouring maggots of some description. That was one point in favour of bullfinches. He had a large consignment of apples sent to him this autumn in which not a single maggot of any kind was to be found, and yet the garden in which the apples were grown were swarming with bullfinches. In his own garden he could never succeed in getting an apple which had not a maggot of some sort in it, but there were were no bullfinches, unfortunately, in his garden. He did not desire to infer in the instances he had quoted that bullfinches were at all times beneficial, but there was no doubt they were in many instances. Another interesting point was, that in his own garden last year the raspberry canes were covered up and protected from the birds. Whether due to that cause or not he could not say, but a very small quantity of fruit was the result, the greater part of it being destroyed by insects, principally caterpillars. This year the raspberry canes were not covered, with the result that a good crop, comparatively speaking, of raspberries was obtained. That seemed to be fairly sound reasoning in favour of birds. His wife, who was an enthusiastic advocate of the protection of birds, and a close observer of their habits, thought that blackbirds did eat snails in almost as great quantities as thrushes did. He thought the author had made a slight historical slip in what he had said as to the extremely interesting alteration in the habits of the kea. Mr. Hooper had said that the kea originally ate nuts, but since the introduction of sheep had changed to eating fat, first from the butcher's shop, next from dead sheep, and it now pecked through the backs of live sheep. He thought as a matter of fact, the historical sequence of the event was as follows. When sheep were first introduced into Australia, the kea, being to some extent an insectivorous bird, proceeded to eat insects off the back of sheep. By accident its beak went a little too deep, and it found that the living fat which underlay the insects, was much more palatable than the insects themselves. It then proceeded to a little further afield and ultimately found itself in the butcher's shop.

Mr. J. OWEN inquired whether it was a fact that bullfinches interfered with apple buds. So far as his

experience went they only interfered with greengage, damson, and plum trees generally and also some currant trees. He had a great number of greengage trees which year by year did not pay for the ground they stood in simply because of the destruction of the bullfinches.

Mr. BUNYARD stated he had found in his father's nursery that bullfinches did attack the buds of young apple trees.

Mr. HOOPER, in reply, said with regard to what Mr. Matthews had said about the bullfinch he wished to make a correction in his paper, namely, that the remark about the seed distribution did not apply to the bullfinch specially, but to seed-eating birds generally, and he believed Mr. Matthews was right in saying the bullfinch prefers unripe seed heads. With regard to seed distribution by birds, Mr. George Abbey had written to him as follows:—"I have mentioned weed distribution to several birds. The reason is, that I have proved that seeds pass through birds undigested. To prove that, I collected droppings, and sowed them in soil, baked to kill all life, and I was astonished to find the number and variety of seed from one ounce of droppings—not hundreds, but thousands." That did not refer specially to bullfinches. It was quite likely that the bullfinch did feed largely on vegetables, but it was really a remark which was intended for more seed-eating birds. He believed the blackbird ate apples on the ground a great deal but not so much on the tree. Amongst the birds protected in Kent which fruit growers perhaps did not approve of entirely were the chaffinch, the whitethroat, and the blackcap, the eggs of the two latter are also protected; and the starling's eggs are protected in the metropolitan district. He was delighted to hear what had been said with regard to the owl and hawk, as he did not have time to say as much as he would have liked of the splendid work those birds did—the owls in reducing the mice, which were injurious not only to the farmer but also to the fruit grower, and the hawks in keeping a check on small birds. He was glad to hear Captain Tailby say that he would take up cases where the pole-trap was in use. With regard to investigation into the food of birds, he wished to mention that the Economic Ornithology Division of the United States of America Department of Agriculture, had, during the last fifteen years, examined the stomachs of 60,000 birds, so as to be able to inform cultivators, as to what grains, weeds, seeds, wild and cultivated fruits, injurious or beneficial insects, the various birds feed upon, in order to decide whether to recommend the encouragement or destruction of each species.

The CHAIRMAN, in proposing a vote of thanks to Mr. Hooper for his interesting paper, said it was 18 years since the last Act was passed, and it was full time an inquiry was held as to its operation during that time.

The resolution of thanks having been carried unanimously, the meeting terminated.

CHINESE RAILWAYS.

The mileage of railways now in operation in China, being built and projected, including the railways constructed under the Manchurian concession, amounts to about 9,000 miles. Railways in China have been classed as commercial, political, commercial-political, and strategical. They may also be grouped according to the nationality of their concessionaires. These would be Chinese, English, German, French, Belgian, and Portuguese. The following, according to the American Consul at Nankin, are the lines which have been or are being built or projected by Chinese initiative and entirely under Chinese control:—Peking-Si-ling.—This line, extending from the capital westward to Si-ling, or the West Mausolea, is nearly 40 miles long. It was constructed by native engineers some years ago, and has since been in continual operation. Changhai-Woosung.—This line, about 12 miles long, was first constructed in 1876, under the auspices of an English firm. For a year there was a good deal of traffic, but the Chinese Government objecting to it being in the hands of foreigners, bought it in 1877, tore it up, and transferred the rails and rolling stock to Formosa. It was not until 1898 thht the Chinese Government reconstructed the line, and at present it is a great success financially. It is to be incorporated as part of the Shanghai-Soochow system. Wuhu-Sengan.—Surveying has only recently begun on this line, beginning at Wuhu, and extending 30 miles to the south-east. At present the work seems at a standstill for the want of money. The line will be built to Sengan, in northern Chekiang, 100 miles, to connect with the railway system of that province. Pingsiang-Chuchow.—This line, which at first connected the coal mines of Anyuen with Liling, a distance of 23 miles, was last year extended 29 miles farther to Chuchow. Nanchang-Kinkiang.—A concession for this line, about 100 miles long, was granted to a Chinese syndicate some years ago, but the matter lay in abeyance until recently the gentry of Kiangsi decided to proceed with the construction of the line. Chengtu-Hankow.—The building of this line was authorised some years ago. It is now stated in Chengtu that the gentry and officials of Szechuen have decided to start at once the construction of the 60 miles between Chengtu and Chiangkou, and thus begin the building of the proposed road to Hankow, which will be the great trunk line crossing the Empire from west to east, as the Peking-Canton line is to be from north to south. When completed the road will be some 700 mile

long. Changsha-Chenchow.—During the early part of 1905, a Chinese syndicate was formed, and obtained the Imperial sanction to construct a railway between Changsha and Chenchow, *viâ* Changseh, and steps are now being taken to carry the scheme into effect. These cities are large and important, commercially, lying wholly within the Hunan Province which abounds in coal. This line would be 200 miles in length. Canton-Whampoa.—Last year Imperial sanction was given to construct this line. It is only ten miles in length, but its importance lies not only in the fact that it is an initiative for a line passing through Swatow to Amoy to connect with the system of Fukien Province, but that Whampao, with its deep and magnificent harbour, might seriously affect the commercial interests of Hongkong. Amoy-Changchou.—This line, which will be about 30 miles long, is being built under the directon of the famous Lin family, formerly the millionaires of Formosa. When completed it is thought that it will be extended to Fuchau. Swatow-Chaochou.—This line connects the port of Swatow with Chaochou, the capital of the prefecture of that name. It is being constructed by Japanese contractors and all the railway materials except rails and locometives are imported from Japan. Canton-Hankow.—This line was to complete the through trunk line from Pekin to Hankow, now finished. Work on the main line has been carried about 70 miles above Canton, where it remains awaiting the settlement of a seemingly interminable struggle for dictatorship between the Viceroy at Canton, the gentry, and the merchants. Peking-Kalgan.—This line, connecting the capital with Chang-chiakon or Kalgan, a distance of 120 miles, is being built with Chinese Government capital and by Chinese engineers at an estimated cost of £900,000. It has been decided by the Government, on the recommendation of Viceroy Yuan Shih-Kai, to extend the line when finished from Kalgan to Urga, the capital of Mongolia, and thence to Kulun on the Mongolian frontier, the funds of which extension have already been provided. Chinanfu-Chenting.—The concession for building this line was originally granted to Germany but being, redeemed, preparations for its construction and the supplying of rolling stock are progressing. Hangchow-Soochow.—The gentry and people of Chekiang province have formed a company for the construction of their own railways. They have appointed a Chinese railway engineer as the chief engineer and are busily engaged in collecting capital. The first line to be built will run from Kungshun bridge, near the settlement of Hangchow, to Kiangkan on the Chentang river, a distance of fifteen miles, whence it will be pushed on to Kashing and Soochow. A wise arrangement has been made among the gentry of the five provinces, Kiangsu, Kiangsi, Anhui, Chekiang, and Fukien, by which the railways in their respective provinces when completed will have a uniform gauge of track and rolling stock, so as to form an inter-communicating system in east central China. Kaifeng-Chengchou.—This is a branch line of the Ching-hau Railway, and connects Kaifeng and Chengchou. It is 50 miles long, and is graded ready for the laying of the rails. Taiynan-Pingyao.—This line is in Shansi province, and the officials and gentry there have decided that the first railway built by them shall connect Taiynan and Pingyao, in the Fen Chou prefect ure,a distance of about 100 miles. They have also decided to build the three following lines, and have obtained the consent of the Shangpu thereto:—(1) From Tatungfu to Kalgan; (2) from Puchon to Tungkuan, in Shensi, crossing the Yellow River; and (3) from Pingyan to Tsachou, connecting with the Taokou and Tsechou Railway, which was built by the Peking Syndicate, and afterwards sold to the Chinese Government.

Dealing next with the question of British concessions, the Peking Syndicate (Anglo-Italian), by certain concessions in Shansi and Honan provinces, secured rights to construct a railway from Taiyuen, in Shansi, to Singan, the capital of Shensi, whence a line is planned parallel with the course of the Yellow River, to connect with Kai-fang, the terminus of a branch line of the Peking-Hankow Railway. The same syndicate has also undertaken to construct a line from Tsechon, on the southern boundary of its mine-fields, to Singan, 250 miles distant on the Han River. To connect the coal-fields or northern Honan, operations were begun upon a line from Chinghua to Taokou, whence the Grand Canal could be reached by the Wei River, thus having water connection with Tientsin. The line has already been completed and ballasted for 90 miles from Taokou. Peking-Newchwang.—This line, 556 miles long, is in operation. It was built with British capital, but sold a year ago to the Chinese Government. It runs from Peking to Tientsin, to which point it has a double track, thence through Tongku, Shanhaikwan, and Kinchow to Newchwang. Tientsin-Chinkiang.—This line is secured by the Anglo-German syndicate. The southern half has been apportioned to the British and Chinese Corporation, and the northern half to a German company. Soochow-Hangchow.—This line, 100 miles in length, and the Kowloon-Canton line, which is under construction and 100 miles long, are secured by the British and Chinese Corporation. The Shanghai-Woosung line is also included in the security. The length of the road is 180 miles, passing through the cities of Soochow, Wusieh, and Chinkiang. It is hoped soon to open it to public traffic as far as Soochow. As regards German concessions, in the year 1889 certain German syndicates and the German Government obtained from the Chinese Government various railway and mining concessions in the province of Shangtung. By the treaty of March 6th, 1898, the construction and maintenance of these railways were to be carried on by a German-Chinese Company, with the title of "Shantung Eisenbahn Gesellschaft." This company was formed in Berlin in June, 1898, with a capital of £2,667,000, and shortly afterwards its headquarters were transferred to Tsingtau. It was soon decided not to con-

struct the line from Chinanfu to Ichoufu, or any other point on the southern boundary of Shangtung province. The Tsingtau-Chinanfu line was constructed during the winter of 1903, and has been working ever since. It had its own postal and telegraph services until recently, when, owing to the strong representations of the Chinese Government, the separate postal service was given up to the Imperial Chinese postal service. Tientsin-Chinkiang.—In May, 1898, an agreement was entered into by which a concession was granted to the Deutsch-Asiatische Bank and the British and Chinese Corporation, represented by the Hongkong and Shanghai Banking Corporation. The northern half of the line is to be under the control of the German Bank, and the southern half is to be under the control of the Hongkong and Shanghai Bank, and is to run to Chinkiang on the Yangtse. The total length of the line is 600 miles. Chinan-Chingting.—A concession was granted to the Germans to build this line, to connect with the Peking-Hankow Railway; but the concession was recently, contemporaneously with the withdrawal of the German railway garrisons, re-sold to China for the same amount as was given for it. Taking next the French concessions. Tonquin-Yunnan.—The line is intended to connect Hanoi in Tonquin with Mengtze and Yunnanfu through the Lan River Valley, a distance of about 200 miles. The line is completed and in working as far as Yunnan. Langson-Lunchow-Nanning.—The concession for this line, which has a length of about 100 miles, was secured in 1889, but so far no work has been done on it. Pakhoi-Nanning.—Nothing has been done on this line. The distance between the two cities is about 120 miles. In the case of the Belgian concessions, the Ching-han or Peking-Hankow line which is about 800 miles in length, was authorised in 1889. The part of the line between Lu-kao-chiao and Paotingfu, some 90 miles, was built with Chinese Government capital, under the direction of British engineers. The concessionaaires of the portion from Paotingfu to Hankow were the Franco-Belgian Syndicate. At present one train leaves Peking and one from Hankow daily, and already attracts many passengers and a certain amount of goods traffic. As regards Portuguese concessions, the Macao-Samshui line is to run from Macao to Siang-shau, thence to Kong Moon and to Samshiu the terminus, where it connects with the Canton-Samshiu branch line of the Canton-Hankow railway. Unlike nearly all the other railways in China, this one will be an entirely commercial undertaking, free from all Government interference or political control. As this line will pass over the Canton and West River delta, many bridges will be necessary, rendering the undertaking a costly one. The distance is about 130 miles. Finally we come to the Chinese Imperial Railways. For the Peking-Tientsin-Shanhaikwan-Newchwang railway a loan was granted from the British and Chinese Corporation. The lines mortgaged as security, and which are in operation, are the 84 miles Peking to Tientsin, double line; 27 miles, Tientsin to Tongku, single line; and 147 miles, Tongku to Shanhaikwan, single line. The lines also in operation, but upon the earnings of which only the loan has a first charge, are the 130 miles, Shanhaikwan to Kinchow, single line, and 130 miles, Kinchow to Newchwang, thus constituting a continuous and complete railway of 526 miles, exclusive of 30 miles for sidings. It has been computed by the engineer-in-chief of the Imperial railways in North China that the capital cost of the intramural line from Peking to Shanhaikwan, a distance of 258 miles (exclusive of sidings) was £1,985,000. At Kaochiao, which means "High Bridge," and is distant 60 miles from Shanhaikwan, there is a branch line running north-westerly for 30 miles, and connecting with the Nanpiao coal mines. These mines are pronounced by experts to be the richest and most valuable coal mines in North China.

THE INDUSTRIAL CONDITION OF BOHEMIA.

Bohemia is situated in the very heart of Europe, on the highway of commerce between its northern and southern ports, and eastern and western markets, a day's distance from the former ports, and only a few hours from the principal cities of Central Europe. Bohemia is a land of extraordinary industrial activity, great agricultural wealth, considerable financial resources, and vast commercial possibilities, and all branches of education are very advanced. It has a population of 6,318,687, or about 25 per cent. of the total population of Austria. This population is about 65 per cent. Czech and 35 per cent. German. There is considerable rivalry between the two races, and this should be taken into consideration in dealing with them. The commercial men speak both languages, but, according to the American Consul at Prague, they generally prefer to be addressed in their own language, and frequently, to deal with their own nationality. Of the foreign languages spoken, French seems the most popular with the Czechs and English with the Germans, but the younger generation is learning both languages, thus speaking four—German, Czech, English, and French. Bohemia covers an area of 20,061 square miles, or about 18 per cent. of the total area of Austria. Of the seventeen divisions of the Austrian Empire, the kingdom of Bohemia ranks second in area but first in industry and commerce. It is also claimed that its land is very fertile and its people industrious. Of the population, about 40 per cent. are engaged in farming and industry; about 38 per cent. are employed in manufacturing and mining; 8 per cent. in commerce, and 9 per cent. as labourers. Only about 14 per cent. of the land is not under cultivation. About one-third of the industrial or commercial firms in Austria are established in Bohemia, representing about 37 per cent. of the

total Austrian industrial and mining industries, and about 26 per cent. of its whole commerce. At Aussig, on the Elbe, on the Saxon frontier of Bohemia, there is a rice milling industry of some importance. In the Erzgebirge district, particularly in the neighbourhood of Carlsbad, the manufacture of musical instruments has been carried on for more than a century, and has so considerably increased of late years, that it is second only in importance to the porcelain industry. Graslitz is the centre where the wind instruments are made, and Schönbach, near Wildstein, is that for stringed instruments, more especially for violins. From Graslitz wind instruments are exported all over the world. Schönbach, with a population of 5,000, is about a three hours' journey by road from Graslitz. There are in the town many manufacturers of so-called cheap violins, and a considerable quantity of these are exported annually to the neighbouring kingdom of Saxony. Coal is produced in and exported from Bohemia. Iron ore, iron graphite, silver and gold are also produced. Mining claims have been taken up by British, French, and local companies, and the gold mining industry, which for many years lay dormant in Bohemia, bids fair to become one of some importance. It may be added that Bohemia's contribution to the Imperial revenue averages about 25 per cent. of the total amount of State taxes received. On taxes levied on real property (land, houses, &c.), the proportion is 22 per cent., and in personal income taxes 23 per cent. In indirect taxes, levied on beer, alcohol, sugar, wine, tobacco, and mineral oil, the proportion was about 27 per cent., giving a fair idea of the industry, wealth, and consuming power of the population of the kingdom.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in September :—

New Charts.—3584—West Indies, channels and anchorages in the Great Bahama bank :—Man of War channel ; Cays south-east of Andros island ; Washer woman's cut. 3587—West Indies :—Haiti ; Fort Liberté bay. 3589—Chile :—Guaitecas islands. 3592—Siam :—Bangkok harbour. 3585—China, north-east coast :—Approaches to the Wusung river. 3575—Japan :—Plans on the west coast of Nipon ; Futam-Wan ; Aikawa Wan.

New Plans and Plans added.—2291—Norway, Sheet II. :—Bergen to Stav fiord. New plan :—Lerdalsöen. 219—Malacca strait : Acheh head to Diamond point. Plan added :—Gighen road. 2284—Plans of anchorages on the west coast of Sumatra. Plans added :—Sinkel road ; Sinkel creek. 2718—Anchorages on the east coast of the Celebes. New plans : — Tomini road ; Togean anchorage. Plan added :—Lambunu road. 2196—Sketch plans of anchorages in the southern part of Celebes. New plan :—Bulekomba and Bintaru roads. 651—Japan : Bungo channel. Plan added :—Amaji ko. 1176—Islands in the South Pacific. New plan :—Niue or Savage island.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners :—1188—The world :—Coal and telegraph chart. 3421—Scotland, west coast :—Broadford bay. 117—Faroe islands. 2300—Baltic sea :—Gulf of Bothnia, sheet V. 2526 — South America, east coast :—Buenos Aires. 1897*b*—British Columbia : — Victoria harbour. 1844—Borneo :—Labuan island. 1857—China, east coast :—Namoa island. China, north coast :—Pei ho or Peking river, sheet I. 5388—China, north coast :—Terminal head to Hai Yung tau. 2415—Japan :—Approach to Nagasaki harbour. 1079—Tasmania. New Zealand : —Port Nicholson. 3033—New Hebrides :—New Hebrides island and New Caledonia.

These charts are issued by Mr. J. D. Potter, 145, Minories.

GREEK MARBLE.

Among coloured Greek marbles of great beauty may be mentioned those of the island of Skyros ; the green marbles of Tirios ; the Cipolino marbles of Eubœa, of two shades of green that blend in broad, wavy lines, that run through the stone ; and the red marbles of Mani, known as Rosso Antico. The latter is of a blood-red colour, often traversed by veins of white, or sometimes found in solid red. According to the American Consul at Athens, a British company owns the whole of the white and blue quarries on the Penteli mountain range, and have spent money lavishly in developing them. The private railway of the company extends fifteen miles from the inclined plains of Mount Pentelikon. Blocks weighing twenty tons are taken to the company's works, whence they are conveyed to the Athens railway, a distance of about eight miles, also over a private line owned by the company. Work at the Penteli quarries is kept in full swing night and day, and about one thousand men are employed. It is the aim of the company to place marble on the market at less prohibitive prices than those which have prevailed hitherto. Blocks weighing as much as forty tons have been taken down to the port at Piræus and loaded on shipboard for export. The Penteli marble is almost pure carbonate of lime, but there is more sparkle in the crystals than is found in Italian marble. Its close texture and high purity of colour have given it an undeniable claim to its description as a "white" marble. But of all the white marbles of the world, perhaps the most beautiful is the finely grained and spotlessly pure Parian marble of the island of Paros. The celebrated statues Venus Milo, the Venus de Medici, the Venus Capitoline, were made of this marble. These quarries, as well as those of the adjoining island of Naxos, have been taken over by the same company referred to above.

HOME INDUSTRIES.

Migration.—Notwithstanding the changes in economic conditions agriculture remains the greatest of home industries, and evidence of contraction, and declining prosperity, can never be received with indifference. The Board of Agriculture has been inquiring into the decline of the agricultural population of Great Britain between the years 1881 and 1906, and it has just published its report upon the facts collected. There is nothing very novel in the evidence submitted, or the conclusions reached, but it is well to have attention directed to the facts by the highest official authority. The total number of replies received to a circular issued by the Board to their correspondents was 248, and in many cases the answers were prepared after consultation with, or reference to, a large number of persons able to afford the necessary information. It may be assumed therefore, that the evidence is fairly representative of the facts, the more so that they comprise census and other inquiries. They show that since the census returns of 1901 there has been further reduction of the men employed on farms, but that the diminution is proceeding at a slower rate than during the twenty years preceding that date. The Report says that, roughly speaking, 30 per cent. of the tillers of the soil have left the country for the town in less than a quarter of a century. In the English agricultural districts, and notwithstanding the general growth of the population, there has been a decrease of 241,152, in Wales of 11,099, in Scotland of 42,376. "Whether we assume," says the report, "that the present rate of the decline in agricultural labour is 10 or 20 per cent. per decennium, or, as is perhaps probable, something between the two, it will be granted that its continuance is a serious social and economic fact." No one will wish to dispute that. Hitherto a decaying rural population has always sapped national vitality, and there is no reason to believe that Great Britain, will be an exception to the rule. Can the migration from country to town be arrested? That is the practical question to which inquiries like that to which attention is being directed do not furnish an answer. The emptying of the countryside into the towns is a deplorable fact. Is it due altogether, or mainly, or to some extent, or not all to preventable causes? There are those who say it is due to a bad land system, and others who are equally certain that, do what Parliament may, it cannot be checked, much less stopped. Probably, as usual, the extremists are wrong, and it is impossible to stop the migration from country to town though it may be possible to lessen it.

The General Rule.—A fact of first importance in this connection is that this migration is not confined to the United Kingdom, although it may have been proportionately larger here than elsewhere. It is found in all countries. Among the older European States there is none more favourably placed for the cultivation of the soil than France. In an exceptional degree the tillers of the soil are owners of it, and in most parts of France the soil itself gives a generous return for the labour expended upon it. Yet the migration from country to town in France is large. In Germany much of the soil is poorer, but the agriculturist is protected by exceptionally high tariffs, and his interests are served often at the expense of the rest of the community, yet in Germany, which until 1870, was essentially an agricultural country, the cities are growing at the expense of the country side. And it is the same in young countries where, as a rule, the tiller is the owner of the soil, and agriculture is pursued under the most favourable conditions. The United States is still largely an agricultural country, but even there the ratio of townsmen is steadily rising, whilst in Australia, the influx from country to town is becoming a matter of serious concern to the statesmen of the Commonwealth. These facts demonstrate that the influences which tend to thin the country districts are not confined to the United Kingdom, and these influences are many. The dissemination of knowledge, and facilities for travel, are at the bottom of the movement so far as the labourer is concerned. A hundred years ago it was not uncommon for a peasant to live and die in the village in which he was born, without ever having visited a considerable town. Nowadays he thinks nothing of a hundred miles journey. The cheap newspaper gives him information of a sort, and he is attracted to the town by the promise of higher wages, greater freedom, more amusement. On the other hand, the landowner and the farmer find it increasingly difficult to derive reasonable profit from the land, and unable to make cereal crops pay, are laying down more and more land to grass with the result, as the report states, that some 2,000,000 acres have passed from arable to pasture during the last quarter of a century, throwing from 60,000 to 80,000 labourers out of employment during that period. Nor is it easy to see how, under present conditions, this state of things is to be changed. Much has been hoped from the increased cultivation of fruit, and something has been done in this direction, but only certain districts are suitable for it, and even then, as in Kent, bad seasons and foreign competition make the industry a very speculative one to growers who, like most English cultivators, are not scientific in their methods. Co-operation might do much, but the English farmer does not take readily to it, and as yet little progress has been made in that direction. And whilst the system of allotments benefits the labourer, there is little to show that even if the Legislature were willing to assist the English tenant, as it has helped the Irish, to become owner of the soil he tills, he would be much better off, or that his sons would be much more willing than they are now to remain upon the land. And of course manual labour is being more and more displaced in consequence of the greatly extended use of drills, horse hoes, mowers, binders, manure distributors, and the like. What with the competition of the foreigner,

the displacement of hand labour by machinery, and the attractions of the towns, the problem to be solved is of the utmost difficulty.

Cotton Supply.—Very hopeful statements as to the expansion of cotton growth within the Empire were made at the annual banquet of the British Cotton Growing Association held last week. There has been a considerable addition to the imports of what may be called Empire-grown cotton this year, and there is ground for the belief that there will be even more rapid advance next year. The need for it grows more apparent every year. By far the larger quantity of cotton produced still comes from the United States, and the home demand increases yearly, whilst much of the exported article goes to the continent of Europe. A few years ago the American consumption of cotton was almost *nil*. Last year the domestic grown cotton retained for consumption amounted to 2,689,432,828 lbs. Ten years ago the per-centage of American domestic product exported was 70·59 per cent., last year it was only 61·55 per cent; and at the present time there is great activity in the Southern States in the building of new mills and the enlargement of old ones. The total number of new mills built during the year ended August 31st last was 22, representing 113,814 spindles. It is true that 14 cotton mills in the South ceased operations in the same period, but the machinery of those mills was practically obsolete, whereas the new mills are splendidly equipped. At the present time the total number of mills in operation in the Southern States is 675; they contain in the aggregate 9,300,000 spindles, and some 190,000 looms. With the new mills, which will begin running next year, the total number of spindles will be roughly 10,000,000, and of looms over 200,000. The additions and enlargements now being made to plants in existence will add another 400,000 spindles before the end of next year. At present the Southern mills in operation are taking about 2,400,000 bales of the annual crop, and when all the plants now in course of erection are at work this quantity will be increased to 3,000,000 bales, or more than 25 per cent. of the total production. And these figures cover the Southern States only. If the expansion is less rapid in the New England States it is still considerable, and promises to continue. Last year the American exports to China were nearly 500,000,000 yards; 79,500,000 yards were sold in the West Indies; and the trade with South America promises rapid growth. Nearly all the American export trade has been developed during the past few years, and whilst the home demand in the United States is growing with great rapidity, the continental demand for the raw material grows larger yearly. Half a century ago the continental demand was insignificant. The contrast between then and now is indicated in the following figures taken from the Statistical Abstract for the principal and other foreign countries just issued (Cd. 3136:—

	1850. lbs.		1905. lbs.
United Kingdom	431,531,091	..	1,983,626,885
France	125,134,091	..	409,151,840
Germany	38,552	..	1,005,839,498
Belgium........	..	..	72,711,991
Russia	4,338,705	..	64,530,059
Spain..........	..	..	147,768,715
Italy	..	..	267,367,731
Total European importation ..	635,381,604	..	4,304,848,900

In 1850, the United Kingdom took over two-thirds of the total American output of cotton to Europe; in 1905 considerably less than half; whilst Germany, which only took 77 bales in 1850, last year took 2,011,675 bales.

Shipbuilding.—The figures which give the tonnage of new shipping built in Scotland for the eleven months ended November 30th, are very remarkable. 1905 was a record year, but considerably more tonnage has been put into the water in the eleven months of 1906 than in the whole of last year, the figures being 603,920 tons, as against 587,930 tons. The average size of the ships has risen considerably, as whilst 16,000 more tons has been floated during the eleven months than in the twelve of 1905, 412 vessels were floated in the latter year, as against 391 in 1906. This average is, however, somewhat deceptive, seeing that it has been increased considerably by the launching of three or four exceptionally large ships. The contrast in the output is not fully represented by the figures given above, because in addition a large number of the smaller class of vessels, and the light draught class, usually shipped abroad in pieces, do not figure in any monthly statements, but are included in the complete returns for the year, so that by the end of December both the number of vessels and the aggregate tonnage will be considerably higher. It is estimated that with the vessels still to be launched, and with the addition of the figures of the "shipped" tonnage, the total output of the year will be very nearly 600,000 tons for the Clyde alone, an excess of 60,000 tons over that of last year. And this notwithstanding the strike.

Iron and Steel.—Last week, Cleveland pig iron rose to 63s. 6d., and at the time of writing it is 63s. 3d. West Coast hematite showed even a bigger rise, at 77s. 9d. On the North-East Coast, steel makers have advanced the price of plates 5s. per ton. Scotch hematite has also appreciated 4s. a ton on the week, and 8s. a ton on the month, at 80s., and even at that price, makers will not part with any quantity. The probability of a shortage in the supplies of hematite iron in this country has alarmed consumers, and the foreigner is ready to pay the price demanded. Home consumers are in an awkward position, for they cannot get a corresponding advance in the manufactured article. All the indications tend to show there will soon be serious deficiencies in the supplies of iron and

steel. The foreign demand is assuming unexampled proportions. The President of the Canadian Pacific Railway Company recently said that his company would gladly buy 10,000,000 dollars worth of cars and locomotives if they could be obtained. The manager of the Paris, Lyons, and Mediteranean Railway Company again has assured the Paris Chamber of Commerce that it would take a year to produce a stock of 1,000 railway waggons now much wanted by the company. There are large contracts in abeyance for the Far East, Canada, South America, and Southern Europe. Altogether it is an anxious time for steelmakers and hematite users, the outlook being anything but clear.

Our Foreign Trade.—The trade and navigation returns for November are among the most satisfactory of a wonderful year. The increase in imports of "raw materials and articles mainly manufactured" is no less than £2,721,054, and allowing £504,746 for decrease in food, drink, and tobacco, and £15,457 unclassified, the total increase in imports is £2,601,934." Our imports of raw cotton were larger by 38 per cent. in value and 24·9 in quantity than for the corresponding month of last year. So with the exports. The total increase for the month was £3,367,013, and of this no less than £2,557,839 comes under the head of "articles wholly or mainly manfactured." Of course the shipments of iron and steel show a large increase, but it is to be noted that the improvement is spread over every class of manufactures wtth the exception of electrical goods, machinery, new ships, and apparel. Taking the eleven months to November 30, the percentage in the imports has risen 8 per cent, and in exports 14·2 per cent. It is a wonderful record, but this country is not exceptional in the great expansion of its trade during the present year. To take our most formidable competitor, Germany, the German foreign trade statistics for October, the latest available, show that imports amounted to 6,347,000 tons, as against 5,239,000 tons in October, 1905, and exports 4,040,000 tons, as against 3,814,000 tons in the corresponding month of last year, and the full extent of the increase is not reflected in these figures, seeing that a large number of articles are no longer measured by weight, and so are not included in the general totals.

CORRESPONDENCE.

OBJECTIONS TO THE COMPULSORY INTRODUCTION OF THE METRIC SYSTEM.

It gave me much pleasure to be present at the Society's meeting on Wednesday last, when Sir Charles Watson read his excellent paper on the Metric System. Unfortunately the two hours at the disposal of the chairman were too short to allow of all those being heard who desired to speak to the paper, and the few remarks I ventured to make were perforce hurried and incomplete. May I therefore be permitted to supplement them by stating that I almost entirely agree with Sir Charles Watson in his arguments against the *compulsory* employment of metric weights and measures and the *prohibition* of the use of our present standards, which, in my view, are the natural selection of the people; with the refinements and adjustments, to suit different trades, which the experience of many centuries has brought about. A radical change, everyone must allow, will be most serious to all concerned, more serious probably than the advocates of the change thoroughly realise. Be this as it may, my desire is to emphasise the fact that after 112 years' experience, France—the initiator of the metric system—can only maintain its legal use by the constant coercion of the Government. The countries which have recently adopted the metric system can hardly be expected to be quite unbiassed in their notions, as the novelty has not yet worn off, and the bureaucrats who introduced the system cannot, if they would, belie a judgment they have comparatively recently given. I, therefore, confine myself to what occurs in France at the present day. I believe everyone who has an intimate knowledge of that country will support me in stating that the metric and decimal system is used there as little as it possibly can be. Precious stones are to-day bought and sold in carats; firewood in cordes; milk in pintes; gravel in toises; grain, potatoes and charcoal in boisseaux; wine in barriques, feuillettes, demi-setiers, and chopines; wood for construction in pieds, pouces and lignes; beer in canettes and pots; sugar and coffee among the poor people is dealt with in livres, demi livres, &c. Cattle dealing is carried on in pistoles and écus and not in francs. I might also refer to the Millerolle of Southern France, the "Charge de Blé," the botte, the sack of flour of, I think, 157 kilogrammes, and a hundred others, but the quotations I make will serve for my argument.

The fact is, the inordinate desire to preserve a ratio of multiples and sub-multiples of ten between the different units has destroyed the usefulness of these units for universal employment. The French people recognise this, and adopt for their trades and industries other weights and measures for every-day use. These they convert into the legal standards when a question of contract arises.

As the chairman read a communication from Lord Kelvin, may I be permitted to reproduce an opinion expressed some ten years ago by one of our recognised clear-thinking men. Herbert Spencer said:—

"From one, who every month has to act as auditor, I have received a letter in which he says:—'I had to go over more than £20,000 of accounts yesterday, and was very thankful that it was not in francs.' This statement coming from a man of business, has suggested to me the question—By whose advice is it that the metric system of weights, measures and

values is to be adopted? Is it by the advice of those who spend their lives in weighing and measuring and receiving payments for goods? Is it that the men who alone are concerned in portioning out commodities of one or other kind to customers and who have every minute need for using this or that division or sub-division of weights or measures, have demanded to use the decimal system? Far from it. I venture to say that in no case has the retail trader been consulted. There lies before me an imposing list of the countries that have followed the lead of France. It is headed 'Progress of the Metric System.' It might fitly have been headed 'Progress of Bureaucratic Coercion.' When fifty years after its nominal establishment in France, the metric system was made compulsory, it was not because those who had to measure out commodities over the counter wished to use it, but because the Government commanded them to do so; and when it was adopted in Germany under the Bismarckian *régime*, we may be sure that the opinions of shopkeepers were not asked. Similarly elsewhere, its adoption has resulted from the official will, and not from the popular will.

"Why has this happened? For an answer we must go back to the time of the French Revolution, when scientific men were entrusted with the task of forming a rational system of weights, measures and values for universal use. The idea was a great one, and, allowing for the fundamental defect on which I have been insisting* it was admirably carried out. As this defect does not diminish its great convenience for scientific purposes, the system has been gradually adopted by scientific men all over the world, the great advantage being that measurements registered by a scientific man of one nation are without any trouble made intelligible to men of other nations.

"Evidently moved by the desire for human welfare at large, scientific men have been of late years urging that the metric system should be made universal, in the belief that immense advantages, like they themselves find, will be found by all who are engaged in trade. Here comes in the error. They have identified two quite different requirements. For what purpose does the man of science use the metric system? For processes of measurement. For what purpose is the trader to use it? For processes of measurement plus processes of exchange. This additional element alters the problem essentially. It matters not to a chemist whether the volumes he specifies in cubic-centimetres or the weights he gives in grammes, are or are not easily divided with exactness. Whether the quantity of liquids or gases which the physicist states in litres can or cannot be readily divided into aliquot parts is indifferent. And to the morphologist or microscopist who write down dimensions in sub-divisions of the metre, the easy divisibility of the lengths he states is utterly irrelevant. But it is far otherwise with the man who all day long has to portion out commodities to customers and receive money in return. To satisfy the various wants of those multitudes whose purchases are in small quantities, he needs measures that fall into easy divisions and a coinage which facilitates calculation and the giving of change. Force him to do his business in tenths and he will inevitably be impeded.

"'But you forget that the metric system is approved by many mercantile men, and that its adoption is urged by Chambers of Commerce.' No, I have not forgotten; and if I had I should have been reminded of the fact by the fears now expressed that our commerce will suffer if we do not follow in the steps of sundry other nations. The fears are absurd. French and German merchants when sending goods to England, find no difficulty in marking them or invoicing them in English measures. And if English merchants imply that they are too stupid to follow the example in a converse way, they can scarcely expect to be believed."

ROBERT KAYE GRAY.

* Spencer here refers to the adoption of the decimal in lieu of the duodecimal system.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

DECEMBER 19.—"Modern Developments of Flour-Milling." By ALBERT E. HUMPHRIES, President of the Incorporated Association of British and Irish Millers. PROFESSOR THOMAS HUDSON MIDDLETON, M.A., will preside.

JANUARY 16, 1907.—Adjourned Discussion on Mr. J. W. GORDON'S paper, on "Patent-law Reform." SIR WILLIAM PREECE, K.C.B., F.R.S., will preside.

JANUARY 23.—"The Straits of Panama." By PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

JANUARY 30.—"Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

Dates to be hereafter announced:—

"The Principles and Practice of Insurance, and their modern Developments." By THOMAS EMLEY YOUNG, B.A., Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association.

"Smoke Prevention in Factories." By JOHN B. C. KERSHAW, F.I.C.

"The Underground Water Supply of the Thames Basin." By CLAYTON BEADLE.

"Engraving and Photogravure." By. J. CRAIG ANNAN.

"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc.

"Cold Storage and Food Supply." By HAL WILLIAMS.

"Modern Typewriters and Accessories." By ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts.

"Motor Omnibuses." By LORD MONTAGU OF BEAULIEU.

"Joinery and Cabinet Making." By A. ROMNEY GREEN.

"Oils, Varnishes and Mediums." By ARTHUR P. LAURIE, M.A., D.Sc., F.R.S.E.

"Sheffield and Electro-plate." By SHERARD COWPER-COLES.

"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G.

"The City of Madras." By SIR JAMES THOMSON, K.C.S.I.

"The Applicability to Indian Rivers of the Italian System of dealing with Silt." By SIR EDWARD C. BUCK, K.C.S.I.

"The Kent Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

DECEMBER 18.—"Basket-Making." By THOMAS OKEY. LEWIS FOREMAN DAY, F.S.A., will preside.

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

February 19, March 19, April 30, May 28.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

JANUARY 15.—"The Progress of the Uganda Protectorate." By GEORGE WILSON, C.B. Brigadier-General SIR FREDERICK J. D. LUGARD, K.C.M.G., C.B., D.S.O., will preside.

March 5, April 23.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

A. D. HALL, M.A., Director of Lawes Agricultural Trust, "Artificial Fertilisers: their Nature and Functions." Five Lectures.

LECTURE V.—DECEMBER 17.—*Potassic Fertilisers. Consumption of Fertilisers.*

JUVENILE LECTURES.

Wednesday afternoons, January 2 and 9, 1907, at 5 o'clock.

"Perils and Adventures Underground." By BENNETT H. BROUGH.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 17...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. D. Hall, "Artificial Fertilisers: their Nature and Functions." (Lecture V.)
University of London, South Kensington, S.W., 8 p.m. Mr. Banister Fletcher, "Greek Theatres and Tombs."
Geographical, University of London, Burlington-gardens, W., 8½ p.m. Col. A. W. S. Wingate, "Nine Years' Survey Work in Northern China and Mongolia."
British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. J. Dibdin, "The Strength and Composition of Mortars."
Actuaries, Staples-inn-hall, Holborn, 5 p.m.
Alpine Club, 23, Savile-row, W., 8.½ p.m.

TUESDAY, DEC. 18...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Thomas Okey, "Basket-Making."
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Henry William Edward Le Fanu, "Mechanical Considerations in the Design of High-Tension Switch-Gear."
Statistical, 9, Adelphi terrace, Strand, W.C., 5 p.m. Mr. William J. Harris and the Rev. Kenneth Lake. "Estimates of the Realisable Wealth of the United Kingdom, based mostly on the Estate Duty Returns."
Pathological, 20, Hanover-square, W., 8½ p.m.
Photographic, 66, Russell-square, W.C., 8 p.m. Mr. Oliver G. Pike, "In Birdland with a Camera."
Anthropological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, DEC. 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Albert E. Humphries, "Modern Developments of Flour-Milling."
Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Admiral J. P. Maclear, "The Guildford Storm of August 2nd, 1906." 2. Mr. Richard Inwards, "The Metric System in Meteorology."
Geological, Burlington-house, W., 8 p.m.
Microscopical, 20, Hanover-square, W., 8 p.m.
British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, DEC. 20...Linnean, Burlington-house, W., 8 p.m. 1. Dr. A. B. Rendle and others, "Botanical Results of the Third Tanganyika Expedition, 1904-5." 2. Mr. F. Chapman, (1) "Fossil Foraminifera of Victoria"; (2) "The Balcombian Deposits of Port Philip."
Chemical, Burlington-house, W., 8½ p.m. 1 Mr. F. R. L. Wilson, "A New Laboratory Method for the Preparation of Hydrogen Sulphide." 2. Mr. V. H. Veley, "The Reaction of Acids with Methyl Orange." 3. Mr. H. Bassett, jun., "Contributions to the Study of the Calcium Phosphates. (i.) The Hydrates of the Calcium Hydrogen Orthophosphates. (ii.) The Action of Ammonia Gas on the Calcium Hydrogen Orthophosphates."
Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. H. G. Brown, "The Track Circuit as Installed on Steam Railways."
Historical, Field-court, Gray's-inn, W.C., 5 p.m.
Numismatic, 22, Albemarle-street, W., 6¾ p.m.

FRIDAY, DEC. 14...North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Journal of the Society of Arts.

No. 2,822. VOL. LV.

FRIDAY, DECEMBER 21, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 2nd and 9th, at 5 o'clock, by BENNETT H. BROUGH, F.G.S., F.I.C., F.C.S., on "Perils and Adventures Underground."

Each Member is entitled to a ticket admitting two children and an adult. A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received. Members who desire tickets for the course are requested to apply for them at once.

CANTOR LECTURES.

Mr. A. D. HALL, Director of the Lawes Agricultural Trust, delivered on Monday evening, 17th inst., the fifth and last lecture of his course on "Artificial Fertilisers: their Nature and Functions."

On the motion of the CHAIRMAN, a vote of thanks for his valuable course of lectures was carried unanimously.

The first lecture will be published in the next number of the *Journal*.

APPLIED ART SECTION.

Tuesday evening, December 18; LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, in the chair. The paper read was "Basket-making," by THOMAS OKEY.

The paper and discussion will be published in a future number of the *Journal*.

CANTOR LECTURES ON IVORY.

Mr. Alfred Maskell's Cantor Lectures on "Ivory, in Commerce and in the Arts," have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can be obtained on application.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, December 4th; the RIGHT HON. VISCOUNT MILNER, G.C.B., G.C.M.G., in the chair.

The CHAIRMAN said he had very great pleasure in calling upon Sir Lewis Michell to read his paper on "The Cape to Cairo Railway." Having regard to the composition of the meeting, he thought that the author required no introduction. There was probably no man better qualified to deal with the subject on which Sir Lewis was about to address the audience. He had not only an almost lifelong acquaintance with Africa, but he was also the intimate friend of that great man by whom the idea of the Cape to Cairo Railway was originated, and he was probably as intimately acquainted as anyone now living with the work and the aspirations of Mr. Rhodes. The author, therefore, came before them with very special qualifications. He also desired to be permitted to add, what was known to many, but perhaps not all present, although it would soon be discovered by them, that Sir Lewis was the master of a literary style which was calculated to give attraction and charm to subjects even less attractive in themselves than that about which he was going to speak.

The paper read was—

CAPE TO CAIRO RAILWAY.

By the Hon. Sir Lewis Michell.

You have been good enough to invite me to read a paper on the subject of the Cape to Cairo Railway as projected by the late Mr. Rhodes. I understand that his friend and ours, Sir Charles Metcalfe, was at one time to have addressed you on the same subject, but was prevented by illness, a fact I deplore for its own sake and also because it transfers the task to one so obviously inferior as myself. I cannot, of course, deal with it from an engineering point of view as Sir Charles is so well qualified to do, but while steering clear of figures and statistics, interesting in themselves but too professional for my powers, I venture to lay before you to-night a few general considerations which seem to me to elucidate the aims and objects of the great scheme.

It is, I know, assumed in some quarters that the idea of such a railway is what the Book of Common Prayer calls "a vain thing, fondly invented," but there is one striking peculiarity about the dreams of the great founder of Rhodesia, that while he dreamt he was generally very wide awake. There are many dreamers in this world whose dreams, however delightful in themselves, come to nothing because they are unpractical; there are also many solid practical business men who leave little mark upon their age because, lacking imagination, they are unable to dream at all. The exceptional man who achieves great things, generally combines the power of dreaming with the practical instincts necessary to enable him to translate his dreams into performances. And of such was Mr. Rhodes. The Cape to Cairo Railway is no unsubstantial dream but a reality, in advance of its age if you like, but still a reality, and already, in great part, an accomplished fact.

As I am not supposed to be dealing this afternoon with that other section of our great pioneering work, the African Transcontinental Telegraph Company, I will content myself with saying here that, after several initial difficulties, the wires have been erected for no less than 1,584 miles. Leaving the Mashonaland Railway at Umtali, it follows the eastern boundary of South Rhodesia, traverses Portuguese East Africa, crossing the Zambesi low down at Tete, serving the well-known missionary station of the Scotch Church at Blantyre, and running through the coffee-growing districts of the Shiré Highlands to Fort Johnston—so named after Sir Harry Johnston—and then onward though the entire length of the British Central Africa Protectorate, touching at many rising villages on the shores of Lake Nyasa as far as Karonga, then westward to Fife and Abercorn, the latter the most northerly point in North-East Rhodesia, and called, of course, after the present Duke, a member, I believe, of this Society, and a loyal and steady supporter of Mr. Rhodes and all his great plans for the civilisation of a continent. From Abercorn the line enters foreign territory, and winding in and out close alongside the eastern shore of Lake Tanganyika, terminates at Ujiji, that historic spot where Stanley found the long-lost Livingstone—a spot which, I say it with regret, though ours by right of discovery, is no longer within our own sphere of influence. Further than this the wire cannot go, except on onerous terms and by permission of Germany; but even in its unfinished state it serves many public and private interests, assists in the preservation of law and order, and is of great and growing commercial value.

It is not so many years ago in point of time that Livingstone and Möhr, Speke and Grant, Baines and, above all, Stanley, roused public interest in the problems and populations of Central Africa. Their journeys were mainly east and west. But what Mr. Kipling well calls the immense and brooding spirit of Mr. Rhodes saw, as in a vision, that civilisation and the trade that follows in its train, might with perhaps greater advantage be introduced into the heart of the Dark Continent from south to north. And instead of resting content with the transient passage of the adventurous explorer and mighty hunter who traversed the pathless forests and unfrequented solitudes of Africa, hatchet and rifle in hand, but left no permanent trace of their footsteps behind them, Mr. Rhodes conceived the nobler but the more practical dream of penetrating the ancient and mysterious continent once and for ever, by laying down from the shores of Table Bay to the blue waters of the Mediterranean, that twin steel rail which has done for the modern world what the great Roman roads did for Europe nearly 2,000 years ago. At what date the idea first occurred to him may, perhaps, never be known, for he was a silent man, not addicted to correspondence, and accustomed to much deep thinking before taking decisive action. But

the following dates are significant and instructive. It was the Conference of Berlin, early in 1885, which drew public attention to Central Africa, by stipulating for freedom of trade and the suppression of the slave traffic in the basin of the Congo. In the same year the Cape Government Railways, thanks to Mr. Rhodes's persistence, reached Kimberley. In the summer of 1888 he suggested, through a now extinct company—the Exploring Company—a prolongation of the line to the then remote and inglorious village of Mafeking. In the same year he persuaded the home Government, after persistent pressure, to declare Matabeleland and Mashonaland a sphere of influence. Great Britain, then as now always unready, was only just in time. Prince Bismarck and President Kruger were neither of them asleep, and but for the masterful energy and driving power of Mr. Rhodes, the entire territory now known as Southern Rhodesia would have passed into foreign and unfriendly hands, and our access to the vast interior would have been barred for ever. In the following year, 1889, Mr. Rhodes having acquired by concession, purchase, or otherwise all the land and mineral rights between the Limpopo and the Zambesi, absorbed the Exploring Company and other similar expeditionary and prospecting ventures, and at once applied for a Royal Charter to enable him, under the authority and control of the Crown, to administer the new and vast dominion thus acquired. In this way a new province of illimitable possibilities was added to the British empire. The charter bears date October 29, 1889, and, as illustrating the impetuosity with which he prosecuted his now fully-developed railway policy, I may draw attention to the fact that on the very same day Mr. Rhodes signed an agreement with the Cape Government to construct a further section of the line to Vryburg. The Government itself was indisposed to proceed beyond Kimberley, then a rising trade centre. Everything beyond that was regarded as partaking of the nature of rash, if not wild-cat, adventure. They preferred to rest and be thankful. But Mr. Rhodes never rested, and his thankfulness was only for favours to come. His life-work was not to be arrested by the timidity of an unimaginative coast colony. He undertook at his own risk and expense to build the 126 miles to Vryburg and he built them. It was soon seen that the extension was going to be a financial success, and the Cape, by an Act passed in August, 1890, exercised its expropriation rights and took over the line. With the money thus set free Mr. Rhodes, under a second agreement, undertook to construct a further section to Mafeking, and it is characteristic of him that, on this occasion, he left out the expropriation clause, and the section, though on Cape territory, is still the property of the Rhodesian railways.

Pushing still north, under other agreements, he left the old colony at Ramathlabama, traversed the entire Bechuanaland Protectorate to Ramaquabam, and at that point entered Rhodesia, and completed ths line to Buluwayo in October, 1898. The capital of Matabeleland, which is 1,362 miles from Cape Town, would have been reached even earlier but for the intervening events of the Transvaal raid of 1896 and the Matabele rebellion of the same date. During this interval Mr. Rhodes had not been idle. Not only was he engaged in opening up railway communication between Mashonaland and its natural port of Beira, but he had succeeded, after a struggle, in obtaining a supplementary charter, in which was enshrined the great principle for which he always strenuously fought, the principle of preferential treatment for British products and manufactures. At this moment, under this charter, which has the force of law, the Customs duties on foreign goods imported into Rhodesia can be varied and raised at will. Against the foreigner, therefore, who erects a discriminatory tariff wall against us we have the power of retaliation. But Rhodesia cannot under any circumstances increase her duties on goods of British origin. And the working men of Great Britain who benefit by what we call the "Rhodes clause" should remember with interest that he wrung it from a reluctant Government, or, rather, he never gained his point till the advent to power of that great Colonial Secretary, Mr. Chamberlain.

From this date onward Mr. Rhodes strove with feverish activity to push the iron rails further on their way. His natural fervour needed no spur, or he might have been spurred by the knowledge he already possessed that he had not long to live. His speeches delivered about this period to shareholders of the Chartered Company, and at meetings of the Rhodesia and Mashonaland Railways, are full of references to the great scheme. Early in 1898 he addressed the first of several important communications to the Secretary of State for the Colonies, with proposals for an immediate extension of the railway to the southern end of Lake Tanganyika, and in hopes of securing a sub-guarantee of debenture interest from the

Treasury. The correspondence has been published in a White-book, and can be studied by all who are interested in following the working of Mr. Rhodes's mind, or who desire to observe with what courtesy and suavity official departments can turn on the cold-water hose or douche of circumlocution and polite criticism on the projects of men who think in continents. It must suffice to say here that the Treasury was very sympathetic so long as no hard cash was required. But Mr. Rhodes's dreams of empire and its huge responsibilities were too far-reaching for the comprehension of an office like the Treasury, which, not unnaturally, looks more to its British than to its Imperial obligations. Negotiations were practically wrecked on the Treasury demand for a counter guarantee from the Cape Colony, which everybody knew it was impossible to obtain.

The only result of the correspondence was the promise of a moderate subsidy for a limited period. It may be convenient here to refer any one who is anxious for further information on this subject to the great speech delivered at the Cannon-street Hotel by Mr. Rhodes to the shareholders of the British South Africa Company on April 21st, 1898. In that speech he paraphrased the correspondence in a striking manner:—

"What I said to them," he remarked, was "are you not aware that England is nothing without her trade? It is the trade of the world that keeps you going. I have cost you nothing so far. I do not ask you for anything, but you have exceedingly good credit. If we borrow, we pay 5 per cent. I want two millions to get to Tanganyika. Back my promissory note, and I can borrow at 3 per cent. If you are nervous, raise the money for only 100 miles at a time, and let each 100 miles pay before you go further. You thus get the railway to Lake Tanganyika, and then you have Kitchener coming down from Khartum."

I must here admit that this picturesque phraseology does not appear in the official White-book. It is a free rendering, no doubt, but conveys the substance, if not the literal text, of Mr. Rhodes's communications.

Another of his speeches, which elicited widespread and appreciative comment at the time was addressed to the shareholders of the Bechuanaland Railway Company, on May 6th, in the same year, 1898.

It had, I think, a great effect in convincing the public that the Cape to Cairo Railway was not only a national obligation, but would materially benefit British trade. Mr. Bryce remarked that the main value of Rhodesia must be sought in the region of high politics. *The Outlook* declared that the occupation of Rhodesia would secure our ultimate predominance in South Africa. The *Saturday Review* pointed out that Mr. Rhodes had grasped the fundamental fact that our island was nothing if not a great workshop, and that the opening of fresh markets was of supreme importance. The *Morning Post* held that a mid-African railway would extinguish the slave trade for ever.

By other journals it was pointed out that Mr. Rhodes had at one time secured the promise from the King of the Belgians of a strip of land on the frontiers of the Congo State, but that this "way leave" had been withdrawn, owing to the diplomatic representations of France and Germany. It is unfortunately true that by the Anglo-German agreement of July, 1890, a wedge of German territory was allowed to be driven between the Nyanza lakes and Tanganyika, just as by another agreement, equally unwise, the same foreign power was granted access to the Zambezi from the westward by means of an extraordinarily shaped wedge thrust forward into our sphere of influence. A Cape to Cairo line all British was thus rendered impossible by the shortsightedness of Ministers on this side, and Mr. Rhodes, bowing to accomplished facts, had to negotiate with Belgium, or, as an alternative, with Berlin. His desire at that date was to extend the rails from Bulawayo to Gwelo, and thence northward over the Zambesi far to the eastward of the Falls, past Lake Bangweolo to the southern corner of Tanganyika. Traversing the lake by a service of steamers, the line would have crossed the strip of foreign territory he hoped to secure, and, entering Uganda at a point between the Victoria Nyanza and Lake Albert Edward, and still proceeding northward, a little to the east of Albert Nyanza, would have linked up Lado and Fashoda with Khartum, and thereafter with Berber and Wady Halfa, and so on skirting the Nile to Cairo. The approximate distance was 6,000 miles, of which 1,800 would have been by waterway. I was an amazingly bold conception, but too Imperial for those home-bred politicians who only England know. Only genius can understand genius. Mr. Rhodes in a public office was like the proverbial bull in a china shop, and his project, regarded as revolutionary and, indeed, explosive, was, doubtless, labelled "dangerous," securely fastened up with red tape, and deposited—this side up with care—in that pigeon-hole in the archives where it still

reposes. His visits to the Kaiser and King Leopold were unavailing to undo the mischief, though his interview with the former was amusingly characteristic of both parties, and would be found interesting in its details were I indiscreet enough to reveal them to you.

Foiled in his efforts to strike due North, Mr. Rhodes entered into contracts to extend the line in a north-westerly direction, through the teak forests, and on to the great Wankie Coal Colliery, a point reached only after his death. From there it was carried to the Zambesi in 1904, the bridge over which being officially declared open by Professor (now Sir George) Darwin, in September, 1905, in presence of the members of the British Association. Even while the bridge was under construction material was pushed across and the line proceeded with. Kalomo, which is 1,733 miles from Cape Town, was reached in May, Mr. Rhodes's flame of fire having communicated itself to his true friend, the late Mr. Alfred Beit, only lately taken from among us. Beyond Kalomo came some heavy work, notably the erection of a bridge over the Kafue river, the longest, as the Victoria Falls bridge was the highest, in Africa. Under the personal superintendence of Sir Charles Metcalfe, the work never slackened, and in June of this year the first engine ran into Broken Hill. Negotiations are now in progress for the construction of another section to a mine called Bwana M'Kubwa, and it is an open secret that a further extension to Kansanshi is under consideration, which would bring the line to the extreme north-west border of the Chartered Company's territories. The greatest credit is due to those who, through evil report and good report, have financed the railways, to Messrs. Sir Douglas Fox and partners, their consulting engineers, to Sir Charles Metcalfe for his untiring personal services, to Messrs. Pauling, the sole contractors, to Mr. G. A. Hobson, who superintended the building of the great bridge, and to many other brave hearts and willing hands.

To all of us the grief is keen and real, that the familiar face of the founder is missing, but he, being dead, yet speaketh, and his works do follow him. What will happen when our boundaries are at length reached it would be premature to conjecture. A large and highly mineralised area—that of Katanga—is reported to exist in the neighbourhood, but as this is a sober relation of known facts, read before a learned society, and does not partake in any way of the nature of a prospectus, I refrain from indulging in those glowing predictions which might be appropriate and customary were I inviting you to subscribe to an issue of additional capital. But that the Cape to Cairo Railway will be abandoned I refuse to believe. There may be delay, but no prolonged or permanent abandonment of the project. The age is not so prosaic as some people imagine. Romance still exists, and men are still swayed by master minds and great ideas. There are still influential circles in which, as occasions arise, the question is sympathetically put, "What would Mr. Rhodes have done?" The continuity of his policy is thus assured. Whether or not the whole line is completed in our time, the glory of its inception and of its partial construction must in justice remain with Mr. Rhodes. Helped he undoubtedly was by able and loyal co-workers, but without his imagination and insight, without his shrewd business instincts, without his dominating personality, very little progress would have been made. Already the direct and indirect advantages accruing from the line are incalculable. It is sometimes scornfully asked whether the traffic between Cape Town and Cairo will suffice to pay the cost of grease for the axles of the wagons, and whether any sane man who makes the through journey once will ever desire to make it again. These cheap pleasantries do not ruffle our feathers. Mr. Rhodes was no fool and he never anticipated that the through traffic would pay debenture interest on construction; what he rightly relied on was the immense stimulus that the line would give to internal development, to cultivation of the soil, exploitation of minerals, greater facilities for occupation of land, and consequently a steady growth of the white population. That he was justified in his forecast I think no one will deny, though the progress made in these directions may be less rapid than an old man in a hurry, like myself, might desire.

Prince Adolphus Frederick, lecturing last month before the German Colonial Society at Berlin, referred with admiration to the improvement visible in British trade on and around the Victoria Nyanza, which he attributed to the construction of the Uganda Railway. He stated that when he first visited the district four years earlier there was practically no white settlers. Now they were pouring in, and fresh applications for land were being daily received. Traffic on the lake, in consequence of the railway service, had largely developed, and new steamers were being built in

England to cope with it. In conclusion he held up our example as a model to his own German countrymen, an unusual and quite refreshing tribute which I could not refrain from quoting to you.

Always remember, that the British possessions in South Central and Central Africa embrace the bulk of the great plateau of the continent, a plateau averaging more than 4,000 feet above sea level, and hence suitable for occupation by Europeans, provided they are afforded the necessary railway communication to and from the coast. Take the case of Rhodesia alone. Vryburg, where our line begins, is at an elevation of 3,890 feet; Bulawayo, the principal town of Matabeleland, is 4,469 feet; Salisbury, the capital of Southern Rhodesia, 4,825 feet; while the Melsetter and Inyanga districts, from which an export of merino wool has already commenced, stand at between 6,000 and 6,500 feet.

Over the Zambesi, in North-Western Rhodesia, formerly known as Barotseland, the plateau is still preserved. Kalomo, the chief town, is 4,090 feet above the sea; Broken Hill, the present terminus, is 3,988 feet above the sea. If we turn to North-East Rhodesia, we find the great Tanganyika plateau, much of it 5,000 and 6,000 feet above sea level, while the altitude of Sunzu has been stated by Mr. L. A. Wallace to be 7,393 feet, of Mamitawa, 7,239 feet, while the Nyika plateau rises to 8,500 feet.

This is not a gathering of the Statistical Society, but I have troubled you with these figures because they do bear on the question of railway development and land settlement. The Cape to Cairo line is not a jungle line traversing steaming valleys and malarial swamps. It aims at conforming as far as possible to the route recommended by engineers, and what is it nowadays that engineers cannot do? It aims at following the contour of the African watershed, and I do not hesitate to affirm that, where the railway runs, there for the most part white people can settle, and in increasing numbers will settle. Thanks to medical science generally, thanks probably to the Liverpool Tropical School of Medicine in particular, the origin and treatment and even prevention of malaria are becoming facts easily obtainable. Mr. Rhodes lived to know this, and he relied, therefore, on ultimate closer settlement, and on the growing value of local or inter-station traffic in regard to passengers, merchandise and produce. The native races are childishly fond of travelling by rail. Throughout South Africa, they are a traffic manager's best customers. It is true they do not travel first-class, indeed they only travel third, because there is no fourth, and, by preference, they would travel in open trucks with their bare legs dangling over the side. But they are consistent travellers. They travel on the slightest provocation, or on no provocation at all. I have seen them in troops arrive at a terminus, and cross over at once into a return train, thoroughly enjoying themselves regardless of blazing sun and dusty track, for they do not take their pleasures sadly, as we are accused of doing. Then, of course, cheap, quick, transmission of labour is facilitated by the railways, which are in this and many other ways, a great developing and civilising factor. Some of you here may have witnessed what I have often seen in the old days, natives walking literally hundreds of miles in search of work. Scant of clothing, short of food, ill, weary, and footsore, they were sustained only by that incomparably sunny temper which characterises the aborigines of the Dark Continent. Now they ride by rail and enjoy themselves. I remember seeing amid the early morning mists enshrouding the Barberton hills, a shadowy troop of Shangans, some of them in the last stage of emaciation, gliding like unsubstantial ghosts, towards the close of a long toilsome trek, to seek work at the Sheba mine. And though alien to my subject, may I add that on arrival there, when the strongest were taken on and the physically unfit rejected as useless, the former invariably shared his rations with the weaker brethren. Wolfishly hungry the workers were, but half their mess allowance went to those who, without it, would have died of sheer starvation. No ethical or moral deduction should be drawn from the incident. The untutored savage was not a Christian or even a philanthropist. He was acting on strict business principles in order that the invalids might the sooner become wage-earning units, and thus add to the wealth of the whole group.

In other parts of South Africa I have seen natives on trek to or from their labour area so utterly worn out by excessive fatigue that to all appearance their wanderings in this world were well nigh over for ever. Much of this will be mitigated or avoided by the Cape to Cairo Railway and its subsidiary feeders. Labour will now have fair play. The mineral and agricultural development of Rhodesia and districts further south will be immensely facilitated by the great trunk line, and its use will

save the native from untold distress. More distant areas will be tapped, new industries will arise, new wants be created, and the whole of Africa will eventually benefit from the extension of the line. A great army of sightseers, missionaries, scientific investigators, sportsmen, boundary commissioners, police, and civil officials, will also reap the advantage of quicker communication with the interior.

But it is, of course, on goods and produce that the line has mainly to rely, and the Chartered Company is now devoting its energies to the task of attracting white settlers, by whose co-operation trade and agriculture, as they develop, will gradually place the railways on a payable basis.

Need I add here that among the many services rendered by the railway it has rendered accessible to the world, or to that portion of it which travels, the grand waterway of the Zambesi and its mighty Falls, across which it runs on a mighty bridge of a single span, designed by one British firm and built by another. and its construction supervised by a British engineer—a structure so noble in its proportions, so delicate in its tracery, that it will remain an imperishable tribute to the skill of our modern bridge builders.

Here, too, the railway scores another triumph, for it is rendering practicable that great conception of utilising the water-power of the Zambesi to generate electric energy on economic lines over a distance double that attained in America: so that one of the assured events of the near future is that the eternal thunder of the great Falls at one end of the wire will ere long be matched, at its other end, by the roar and crash of the many thousand head of stamps employed by night and day in the largest mining centre in the world.

For my part I foresee the time when our achievement in bridging the Zambesi will appear but an incident in this great undertaking. We are already out of the hearing of the roar of the Victoria Falls; already beyond the furthest point which owned the Matabele sway. We are already in the heart of Barotseland, and practically nobody, in this age of progress, can say to us "Thus far shalt thou go, and no farther." We are investigating the economic value of our teak forests for wood-paving the streets of Colonial towns; we are hoping to exploit the waters of the Zambesi for carrying electrical power to Johannesburg; we are sending down gold and diamonds for use and ornament; we are working our railways with our own coal; we are beginning to ship zinc and lead ore from Broken Hill, and ferrochrome ore from Selukwe to harden steel plates for the British Navy, and, finally, we shall ship copper for your telephone wires, and rubber for your motor-cars. All this actual and potential traffic is due to the waking dream of one great man. Here, at the heart of the Empire, no statue has arisen to the arch-Imperialist, but travel in South Africa and you will feel his spell; you will look around you and see his monument; a monument more durable than brass, for it is the monument of high achievement, and of duty nobly done.

We shall soon, from the observation-car of a railway carriage, look out upon the Congo State. Are we to stop there? It is unthinkable! Mr. Rhodes would not have stopped there. After his manner I seem to dream. I see, as in a vision, a thread-like, serpentine double rail athwart the entire continent. South to North I see the coloured races being conveyed to and from labour centres in health and comfort. I see our crowded and over-crowded areas here pouring out thousands of white men, to build, as Mr. Rhodes wished, "more homes" under brighter skies and happier conditions. I see additional employment here for our own people in manufacturing articles for those who have transferred their domicile to Rhodesia and Central Africa. I seem to see long streams of wagons made in Birmingham and Lancaster, drawn by powerful engines made at Leeds and Glasgow, travelling from the Cape of Good Hope or Beira, ever northward, over rails made in South Wales, and conveying mining machinery, agricultural implements, and articles of necessity, and eventually of luxury, from every manufacturing town of Great Britain. And I see those same wagons coming south, laden with coal, copper, and many other minerals, with timber, wool, and hides and skins, with ivory, tobacco, cotton, rubber, ground-nuts, valuable fibres, and other products of a sub-tropical country. I see the silver tie of sentiment which now binds Britain to her African colonies, strengthened by the even stronger band of mutual trade interests. I see the slave trade finally and for ever eliminated from those remote corners, so full of cruelty where it still flourishes. I see Christianity and civilisation advancing northward hand in hand, to found in Africa another of the vast empires of the world and of the dim future, whose originating centre will be these islands of ours, at once so small and yet so great. And, as I dream, I seem again

to see the wonderful man who now sleeps his last sleep amid the granite kopjes of his own Matoppo Hills. He is at length at rest, but his face is looking northward; and we do well to remember him who, in his all too short life, gave to us, amid many high and fruitful ideas, the wonderful conception of a railway from the Cape to Cairo.

On one point the progress of the railway is watched in certain quarters with feelings of apprehension, and I will not deny that the apprehension is justifiable. We are, as we go north, approaching that central tract of Africa which is being devasted and depopulated by that terrible scourge, the sleeping sickness. The danger feared is that easier, quicker, and more continuous intercommunication may tend to spread the disease to other centres. I can only say that we are alive to the risk, and if, as the Royal Society pointed out last week, the British South Africa Company, with all the immense financial responsibilities resting on it, has recently spent £36,000 in helping science to determine an arc of the meridian, we shall not grudge time, nor trouble, nor expense to protect the white and native populations of the territories within our jurisdiction from the horrors of the sleeping sickness. I have myself within the last few days had an interview with Dr. Todd, than whom there is no higher authority, and he has pointed out the nature of the precautionary steps to be taken to discover and isolate cases and prevent any extension of the area which the disease afflicted. For my part, I venture to think that, with intelligent care, the railway may help and not hinder the devoted medical men engaged in fighting the sleeping sickness, sometimes, as in the case of Dr. Tulloch, at the risk of their own lives.

Before bringing this paper to a close, let me remind you that, while our progress to the North has been fairly rapid and reflects credit on the financiers, engineers, and contractors, it is not the only progress that has been made. I have already quoted Mr. Rhodes's strikingly picturesque dream of "Kitchener coming down from Khartum." Lord Kitchener has long since left Egypt, and served his country well in another part of Africa, but his spirit still haunts the land of the Pharaohs—the strong will still seems to dominate the Sudan. There, too, the railway progress has been considerable. From Cairo or Alexandria southward to Assuan, a distance of 590 miles, the line is constructed, and another 560 miles between Wady Halfa and Khartum, while a further extension of 410 miles to Usambara is, I believe, projected. In the aggregate, the line from the north, completed or contemplated, is thus about 1,600 miles and from the south rather more than 2,000 miles. Add to this the long Tanganyika waterway and you will see that the great enterprise is already far advanced. I do not believe that the courage and tenacity of our race are failing us, and some of those here present here to-night may live to see the land of the Pyramids and the Sphinx linked up with that cape of storms now called the Cape of Good Hope, round which that intrepid Portuguese sailor, Vasco da Gama, drove his crazy barque a little over 400 years ago. I have finished. I trust I have not wearied you. It has been my aim to avoid the dry bones of tabular statistics, but to give you, in very general terms, an outline of the origination and partial completion of a line destined, in my opinion and, I trust, in yours, to regenerate a continent, to bring peace and prosperity to Africa, and an expansion of trade to the country whose citizens we are and whose faithful servants we are proud to be.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said he felt sure that, after listening to the paper, the audience would feel that any promises he had held out in his introductory remarks had been more than amply fulfilled. As owing to the fact that he had to keep another engagement, he would not be able to be present when the vote of thanks was passed to the author which he so amply deserved, and which would no doubt be cordially accorded, he would like to express to Sir Lewis his personal thanks for the delightful manner in which he had brought forward the subject. There were only two ideas which occurred to him while Sir Lewis was speaking which he desired to be allowed briefly to mention. The first was the impression which was made upon his mind as the author went over the stages of the familiar story of Mr. Rhodes's great achievement—the impression of the last, and perhaps most memorable instance in which the power of this country had been extended and its prosperity enlarged by the efforts of individual Britons, in the teeth of the indifference, almost the hostility, of British Governments, and sometimes, it might almost be said, of the British people. That was a familiar story, and it was one which gave ground for hope, even at times when, for other reasons, the prospects of Imperial expansion in our existing dominions might seem somewhat clouded. There was always the ultimate reliance upon the courage, initiative, and patriotism of the individual Briton.

The other point which struck him was the lesson which the story afforded of the stages through which all those great enterprises, like the Cape to Cairo Railway, seemed necessarily to pass. First, there was the brilliant stage, in which the imagination of some great man was fired with an immense scheme of this kind, and in which, by his eloquence and his contagious genius, he carried his fellow men along with him, and obtained the material means which were necessary for its realisation. In that stage there was all the splendour and brilliancy of hope, and there was a glorious vista of a great unknown future. Then came the stage in which the work was realised, or partly realised, and the immediate consequence was that the results, in the first instance, were vastly below what people, at the inception of the enterprise, rather unreasonably expected. Then came the day of the critics, the depreciators, the minimisers, and the people who were always only too happy when they could point out the failure, or what they conceived to be the failure, of any great scheme. That lasted for a time, but it had to be passed through, because a great trunk line of any kind had to create, as it were, its own market, and, indeed, its own world. All the civilisation which it was intended to serve necessarily came after it; it was the basis on which the whole fabric was built, and as long as the base alone was there people said, "Where is this splendid building which we were promised?" He was old enough to remember the time when people used to speak in contemptuous terms of the failure of that great enterprise, the Canadian Pacific Railway. He thought those people had been wise enough to forget their criticisms to-day. But there was a third stage ahead of it, a stage which the Canadian Pacific Railway had already reached, the stage in which all that the line was intended to render possible had come about; and then, though often in forms different from what was originally supposed, the great idea of the original planner found its full justification. They would live to see that stage in the case of the Cape to Cairo Railway, as they had seen it in the case of the Canadian Pacific Railway, and he thought they would see the full material justification of that great enterprise a long time before the whole work was completed. It was possible (though he hoped it might not be the case) that there would be some delay, even considerable delay, in joining up the two ends of the line. But long before those two ends were joined, the existing portions (and he was speaking now more especially of the South African portion, which was more particularly connected with the conception and the work of Mr. Rhodes)—would have fully justified all the great efforts which had been made to create them. It was the chief object of a line like that, not so much to connect its one extreme end with the other, as to connect those otherwise isolated points along the great backbone of the Continent, from which lateral lines ran to the coast, by which trade was developed. It was undoubtedly, in the first instance, the lateral lines which were of importance for trade. He desired the audience, however, to look at the difference between the position of having a number of points right up the centre of Africa, connected with the coast by lateral lines and entirely isolated from one another, and the position which the trunk line created of uniting all those isolated points with one another, and creating internal roads of communication which alone could bind those isolated stations together. It was a matter of enormous importance anywhere, but its importance was all the greater in a country situated as Africa, and especially South Africa, was, in which the points of greatest importance were isolated points on the central high plateau, separated from one another by great distances. They might each have their separate communication with the sea, but the trunk line linked them together, and in that way alone could the scattered centres of civilisation in the heart of Africa be united into one country, and effectively brought within the influence of the British Empire. He wished to express his conviction, that although they might at the present moment still be passing through the second of the stages which he had described, they would enter the third stage before long, the stage in which the immense expenditure, not only of money and of work, but of thought, courage, and devotion, which had gone to carry that great line of communication from Cape Town to very nearly the centre of Africa, would begin to meet with great material rewards. Needless to say they would all rejoice to see them for many reasons—for the benefits which South Africa would derive, and for the advantages to be gained by the trade and the industry of this country; but some would rejoice for another and more personal reason, namely, because those who recognised from the first the greatness of the conception, and who realised from personal knowledge the greatness of the man in whose brain it originated, would be glad and proud to see an achievement which would compel the admiration which they themselves had always felt even from the most critical and the most unwilling.

Sir DOUGLAS FOX, M.Inst.C.E., remarked that, in the absence of Sir Charles Metcalfe, who was on his way home from a second visit to rail-head beyond Broken Hill, he desired to thank the author of the paper for the very kind way in which he had spoken of their firm and of the contractors. His mind was carried back to fifty years ago, when he helped his father, Sir Charles Fox, in connection with the first railway in South Africa—from Cape Town to Wellington and Wynberg. There was a long jump from that time to the day when their late lamented chief, the Hon. Cecil Rhodes, communicated with his firm, and asked Sir Charles Metcalfe and himself to lay down the engineering details which had since formed the foundation for the work which had been described by the author. The system had had one great advantage in the fact that Sir Charles Metcalfe from the first had had the location of the railway, and, therefore,

the whole of it had been laid out with a definite object and in a definite way, and by his own personal observation. He had been largely assisted by those connected with the firm of contractors. He did not think they could speak too highly of the way in which the work had been carried out by Messrs. Pauling and Co. They had enjoyed special advantages from their intimate knowledge of the country, from their most judicious treatment of the natives, which had enabled them to get labour when nobody else could get it, and by their courage in dealing with great difficulties connected with transport, the supply of water, and other necessities which engineers fully realised. A great deal of the rapid progress had been due to the continuous work of the contractors right from the beginning, and he, therefore, felt bound to bear tribute to the excellent way in which they had carried out their duties. His firm particularly thanked the author for the kind way in which he had spoken of them. He desired especially to thank Sir Lewis for the mention he had made of his (Sir Douglas's) partner, Mr. Hobson, to whom so much credit was due in connection with the Victoria and the Kafue bridges, the whole of the details of which came under his especial care. They were still with their faces firmly set northward. They had passed over great difficulties, and he did not think they had any greater obstacles in front of them than they had already surmounted. He believed they would have just the same earnest support from the contractors as they had always received, which had been such a great factor in the success of the undertaking, and he believed that before long the railway would reach the utmost limits of the British possessions. The more that was seen of the opening up of the country, the more practical men felt convinced that, in the Rhodesia railways, there was a noble and glorious future, not only for the shareholders but for the British Empire.

Major E. H. M. Leggett, R.E., D.S.O., said that as one who had been very humbly connected with development work in Africa, and who had felt what it was to work under that vast brooding spirit which hung over Africa, he felt it his duty to rise and confess the faith that was in him. The spirit which was left behind by Mr. Rhodes was no small thing, and its material symbol was the Cape to Cairo Railway. But, great as was its material value, this great work of genius conceived by a mighty brain and forged by brave men, had had a remarkable effect upon the character of all who were brought in touch with it, and influenced many in the performance of their small daily avocations. It was only practically a few years since this great conception arose in the brain of Mr. Rhodes, but demands for railways were now being received from Nigeria, Uganda, British Central Afriea, and other possessions. The Uganda Railway, which, curiously enough, was not in Uganda at all, was built almost by accident, certainly without anyone realising the enormous value it would prove to be in the development of the colony; and the position in Nigeria and British East and Central Africa was exactly the same. The men who were developing those countries were inspired by the conception of Mr. Rhodes, and by the forcefulness with which he made that conception a living fact. With regard to the future of tropical Africa, it possessed rich soil, fine uplands in which white people could make their homes, and a climate which, though tropical, was suited to white planters. On the lower levels the soil could produce two crops a year over large areas, and the staples were cotton, indiarubber, fibre, and other necessities of the world's commerce. Those were the industries which the African Empire held out to them as the reward of enterprise, the conception of which originated in the Cape to Cairo scheme. He claimed that the colonial work of the twentieth century was the development of the Central African provinces. Sir Lewis Michell had said he had great faith in the British public; but it must be remembered that when Mr. Rhodes, less than ten years ago, asked the Imperial Parliament to help him, instead of doing so they debated the question of whether trams should run over Battersea-bridge. He hoped that a paper such as they had just heard could be read annually, so that the importance of the scheme might be kept before the eyes of the public and the memory of the great man who conceived it might not be forgotten.

Sir Charles B. Elliott, K.C.M.G. said that as he held a kind of brief for the Cape Government in connection with his appointment as Honorary Special Railway Commissioner, he thought it was his duty to comply with the request made to him to join in the discussion. Sir Lewis had referred to Mr. Rhodes as a dreamer, but Mr. Rhodes once called himself a painter, as he had succeeded in converting a territory which belonged to the natives into British territory, and thus painted that portion of the map red. He (the speaker) was fortunate enough in being asked by Mr. Rhodes to construct the first portion of the line from Kimberley to Vryburg. Mr. Rhodes requested the Government to sanction his appointment for the purpose, the whole arrangement being settled in two or three minutes. Mr. Rhodes gave him *carte blanche* in the construction of the railway, and he went on with the work, not as a Government line, but as a line that would be made by an ordinary contractor. But, in a clause in the contract, the Government had the right to take the railway over as soon as it was constructed, at cost price, and that course was adopted at a cost certified by himself. The benefit to the Cape of the railway had, he believed, already been very real, and he hoped it would increase. Although there were rival ports which considerably interfered with traffic to and from the Cape, yet he felt sure that every facility for traffic must be, more or less, a help to all the ports. It was quite true that certain ports might suffer. He found in his experience that when a terminus of the railway was made in a certain town or village the place prospered, but when the

railway was extended the place lost its prosperity and reverted to its normal condition. That was a condition which many railways had to face. In America the railways were sometimes made, and the towns were then built along the railways. In Africa, to a very large extent, the railways had been constructed, not according to the bee line, but according to the position of the towns or villages which it was expected to serve. That was the reason why a very straight line of railway was not generally seen in Africa, as it was in some parts of America. The author had referred to the large teak forests of Rhodesia, and had suggested that the wood might be utilised for paving the streets in colonial towns. He took a special interest in the subject when he was in Bulawayo, and brought a moderately sized log of teak wood back with him, being very much struck with its beauty. He had seen articles of furniture made with that wood in the club house at Bulawayo, and Mr. Rhodes had a bedroom suite made of similar wood. It had a black vein, which reminded him of a black-veined fish in South Africa well known by the name of "galjoen." If it was polished on an emery wheel revolving at 3,000 or 4,000 feet a minute, it obtained a surface like glass, and made a more polished surface than he had seen given to any wood in any part of the world. Last year he received a sleeper made of Rhodesian teak, which he had cut into various portions and sent to Messrs. Holtzapffel, the well-known lathe makers and turners, but he was disappointed to find it did not turn out like the previous specimens. He thought such wood would be more suitable for handles of tools than anything else. Evidently there were different kinds of teak in Rhodesia. When he was general manager of the Cape Government Railways, he calculated the cost of the transport of the wood from Rhodesia, and he feared it would be too expensive to bring it down to Cape Town. His impression was that it would have to be carried to the eastern coast and then conveyed by steamer, if it was to be utilised for the purpose to which the author had referred.

Upon Lord Milner vacating the chair, his place was taken by the Chairman of the Colonial Section (Sir Westby B. Perceval).

Sir David Gill, K.C.B., F.R.S., said he was sure that all present desired to thank Sir Lewis very sincerely for the warm and weighty words he had used in describing the Cape to Cairo Railway, and for the beautiful account of his dreams of the future progress of the country. For his own part, he could not speak from the point of view of a general manager of a railway, but he had been interested in a parallel scheme, the extension of the Arc of the Meridian through South Africa, and with the assistance of Mr. Rhodes and the British South Africa Company, that work was somewhat ahead of the railway. They were parallel instances of the progress being made in South Africa, and they were advancing the cause of science, of commerce, of civilisation and of progress together. He had the honour of being asked to the opening of the railway at Bulawayo not many years ago, and he should never forget the remark made to him by an old missionary there, who said that the first time he came to Bulawayo it took him eighteen months to get there from Port Elizabeth, travelling as fast as it was possible for him to do, because he had to stop in the dry season in certain places, and wait till the grass grew before his oxen could get on again. That was a simple illustration of the enormous advantages conferred upon the country by the construction of such a railway. He remembered not very long ago tasting the best coffee he ever tasted in his life, and he wished he were in the position of the man in Pears' Soap advertisement, when he said he had since "used no other." The coffee came from Lake Nyassa, and he knew there was a splendid opening for coffee growing in that district if labour could only be found. The author had mentioned one fact in a casual way, the immense importance of which he did not think was realised. Sir Lewis mentioned that chrome iron, which was required for the construction of the hardened plates used for the protection of men-of-war, had been found in Rhodesia. The author did not mention, however, the most important fact that, so far as they knew, until the discovery was made in Rhodesia, Turkey was the only source of supply of that particular chrome iron. It was not very long since England was in serious diplomatic difficulties with Turkey, and had any trouble ensued, this country would have been deprived of the power of building men-of-war protected by hardened iron plates. The Chartered Company had reported that they had mountains of chrome iron, and Rhodesia had already sent three shipments of, he believed, 800 tons for the use of the British Navy. That showed in one way how tremendously important might be, in fact already were, the products of the country, not only to South Africa, but to the Empire, from the creation of the railway. He felt sure that the railway would in the future make sure and steady progress, as it had already done. The spirit of Rhodes still abided in the directors of the British South Africa Company; and with the power they held in their hands, and with, he hoped, the money of every true-hearted British citizen, if necessary, the work would go on until the dream of its great originator was realised.

Commander B. Whitehouse, R.N., said he was not very well acquainted with the part of Africa through which the Cape to Cairo Railway was intended to run. He noticed it had been said that the railway did not appear to be very straight, but that it deviated to the west in the southern part to the Wankie coal fields. In the same way, when it arrived at the north end of Lake Tanganyika it would also probably have to deviate to the right to the Victoria Nyanza, because that was certainly the shortest way to the coast. Looking at the map it

would seem that, at the edge of British East Africa, was the straight line to the Victoria Nyanza, and the shortest way to Tanganyika, was to go up across the Uganda Railway and down by a railway which must eventually be built. The Germans quite saw that a connection must be made, and were likely to make a road. He had just come from the south end of the lake, where he had heard it suggested that motors should be run on that road. If it was proposed to make a road along which motors could travel, it would also be necessary to build permanent bridges, and if all that work had to be done, they might just as well make a rail road at once and be done with it. He had also heard the remark made that the trade along the south part of the railway would not pay for the axle grease. A good many remarks like that had been made about the Uganda Railway, and, therefore, it was very gratifying to know that during the last six months the working of the Uganda Railway had resulted in a profit of £40,000. It had been stated that one wagon a month on the railway would suffice for all the needs of Uganda, but it was now carrying so many loads that it was rather tired and could not carry them all. The consequence was that two steamers, in addition to the two already employed, were being built for use on the lake, and he did not think there was the slightest doubt if the Tanganyika route was opened up that the four steamers would have to be increased to six. There was plenty of water for the steamers nearly all over the lake, and he did not think there was the slightest doubt about the traffic. The original idea of the railway was to touch the nearest point to the coast. That had been carried out, and there were now many loads going across the lake to Tanganyika and the Congo State.

Sir WESTBY PERCEVAL said he was only a *locum tenens* for the Chairman, and in that capacity it was his privilege to ask the audience to cordially thank the author for his paper. But before doing so he desired to tender to Lord Milner the thanks of the Society and the audience for his attendance at the meeting, which had added so much to the interest of the paper. The paper was of great value, and drew attention to a subject about which he was afraid the British public as a whole knew very little. Personally he had no connection with South Africa, but he was a Colonial; and no one recognised more than he did, the value of Colonial expansion to the people of this country. How the people of this country could think that anything would tend to their ultimate benefit so much as the expansion of British possessions beyond the seas he could not imagine. It only remained for him to ask the audience to join with him in according to Sir Lewis Michell an exceedingly hearty vote of thanks for his paper.

The resolution was carried unanimously, and Sir Lewis Michell having expressed his acknowledgements the meeting terminated.

FIFTH ORDINARY MEETING.

Wednesday, December 19th, 1906: THOMAS HUDSON MIDDLETON, M.A., Professor of Agriculture, Cambridge University, in the chair.

The following candidates were proposed for election as members of the Society:—

Baltischwilder, J., Grand Hotel, Zurich, Switzerland.
Chambers, Alexander George, 8, Khersonskaja, Onlitsa, St. Petersburg, Russia.
Hobsbaum, Isaac Berkwood, F.C.S., 79, Claremont-road, Forest-gate, E.
Ijuin, Admiral Goro, I.J.N., The Admiralty, Tokio, Japan.
Kerr, George A., Lynchburg, Virginia, U.S.A.
Newman, Arthur D., Messrs. Fraser and Chalmers, Limited, P.O. Box 619, Johannesburg, Transvaal, South Africa.
Trimmer, Lieut.-Col. Augustus Richard, Parkstone, Beckenham, Kent.
Walker, Captain Herbert Marriott, 228, Mackenzie-road, Beckenham, Kent.
Wyllie, Lieut.-Col. Sir William H. Curzon, K.C.I.E., M.V.O., 10, Onslow-square, S.W.

The following candidates were ballotted for and duly elected members of the Society:—

Brookesmith, Frank, Dalrymple-road, Appleby, Invercargill, New Zealand.
Faulkner, P. Leo, A.S.P., Shillong, Assam, India.
Horsley, Gerald Calcott, F.R.I.B.A., 2, Gray's Inn-square, W.C.
Rouse, Herbert James, c/o. Messrs. Mackinnon, Mackenzie & Co., Ltd., Strand-road, Calcutta, India.
Wood, Thomas Alexander Stephen, Penshurst, Prince of Wales-road, Carshalton, Surrey.

The paper read was—

MODERN DEVELOPMENTS OF FLOUR-MILLING.

By ALBERT E. HUMPHRIES.

Flour-milling involves mechanical separations only — no fundamental change in the constitution of our raw material and its products. We have to remove dirt and extraneous matter from the wheat, and, having done so, to effect as perfect a separation as possible of husk from kernel. In doing so we reduce the kernel to the powder known as flour or wheaten flour.

I want to avoid the unnecessary use of technical terms, and the first evidence tendered of this good intention is the use of the terms husk and kernel. The husk, known

commercially by the generic term of millers' offal, is divided according to size into various commercial grades, sold under various names in different parts of the country, such as bran, pollard, randans, gurgeons, sharps, toppings, shorts, middlings—all representing from the microscopist's point of view a jumble of the various skins of wheats known to him, mixed with a proportion large or small of kernel. For let it be clearly understood that few if any of the separations we make are perfect. Flour contains some amount of husk, offal contains some amount of kernel, the excellence of our milling, according to our own standards, depends upon the degree of perfection attained in our work of freeing the wheat first of all from impurities, and then on the degree of perfection attained in effecting a complete separation of husk from kernel. I shall, for the sake of simplicity throughout the greater part of this paper, speak of our numerous products of cleaned wheat as in essence two only, flour and offal, kernel and husk. Later on I shall briefly refer to another one, germ, but at this present moment there is no necessity to dwell on that.

Change in the Nature of Wheats Available.

For a proper comprehension of my subject, it is necessary to consider the wheats available for the use of British millers in the last thirty years. In the years 1868 to 1872 inclusive about 60 per cent. of the flour consumed in the United Kingdom was made from home-grown wheats. In the last five seasons we have produced at home only 20 per cent. of the wheats consumed. This difference between the respective periods is sufficiently striking for the purposes of my present argument, but it is important to bear in mind the great difference in the sources of our foreign supply. In 1872 we obtained a large proportion of it from Russia, and it is interesting to be reminded that we received in that year substantial quantities of wheat from Germany, France, and Chili. Almost all of those wheats may be described as mellow with relatively tough skins. From Russia we still get large quantities, but they form a smaller proportion of our total foreign supplies than they did in 1872, and from the other countries named we get practically no wheat nowadays. Then we obtained a substantial quantity from the United States and a little from Canada, but from the miller's point of view the character of the wheat, having regard to the way it behaves in the process of milling, has largely changed. The wheat grown in the Eastern States and Lower Canada was not dissimilar in its characteristics to English, and it was from those parts that the wheat exported to us was drawn. But the invention of the self-binding harvester revolutionised wheat-growing, inasmuch as its growth was not so much restricted by the available supply of labour at harvest time, and as a consequence the wheat fields of the United States and Canada were moved westwards in both countries, into the "North-West" and Manitoba respectively. There the farmers grew wheat, which behaved quite differently in the mill to the older sorts. Furthermore, in 1872 we obtained nothing from India or the Argentine Republic, and only a trifling quantity from Australia. Now we obtain huge quantities from these new sources of supply. The bearing of these facts on my subject is this. In milling we are bound to use force in grinding, and the method of applying this force has a most important effect upon the division of husk from kernel, but a factor in the case almost or quite as important as the method of grinding, is the character of the wheat operated upon. If the wheat be mellow, and possesses a tough skin, a method of grinding involving much friction will not pulverise the husk to any great extent, but if the wheat be hard, and possesses a friable skin, such a method of grinding would pulverise a substantial proportion of the husk so that the quality of both the flour and the offal would be lowered. The bread produced from such flour would be exceedingly dark and unpalatable, and the owners of horses and cattle would complain of the offal; many would abstain from buying it.

A gibe aimed at British millers was that we let the Hungarians and Americans get the start of us in the adoption of modern milling, and although we are to-day second to none in the art of milling, and in the skilful application of it to modern requirements, we have to admit that the gibe was based on fact, so that we lost in the early days of roller milling a large amount of trade, but it seems to me that this slowness of ours in adopting modern methods was not due exclusively to our native and national conservatism, but to an application of the axiom that "necessity is the mother of invention." Modern milling had its inception in Hungary. The best varieties of wheat grown in that country are as good as any the world produces, but they are hard, and have friable skins. The necessity for handling

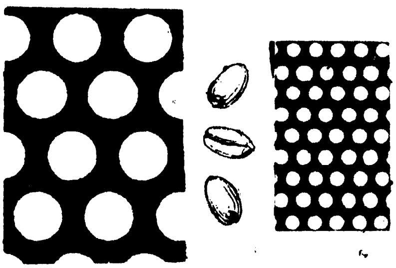
them gently in milling was urgent. No known implement for grinding wheat, not even the millstone at its best, can at one reduction resolve wheat into finished flour and finished offal. That was the aim of millers forty years ago, but it was not achieved. They obtained an intermediate product which was neither flour nor finished offal. If that were again ground on millstones, the finished flour obtained from it was too dark, even for those days, so the miller made as little of this intermediate product as possible, and frequently sold it without further treatment for making coarse biscuits or as pig food. The trouble was accentuated when wheats were hard. The Hungarians discovered that by an application of wind currents, called purification, it was possible to eliminate the particles of light specific gravity, largely offal of an awkward size, from this intermediate product, and that if the purified stock were ground by rolls, flour of first rate quality could be obtained from it. The improvement was so great that instead of making as little as possible of this granular intermediate stock, the object became to make as much as possible. About this time the great wheat lands of Minnesota and the Dakotas were being opened up, and the grain they produced was altogether harder and had a more friable skin than the wheats grown in the Eastern States. The millers in those districts could not make flour by millstones from their wheats, which could compete in the markets of the world with the flour made by millstones from the more mellow wheats, and with American quickness of thought and action they adopted and developed the new ideas of the Hungarian millers. The position of British millers was then exceedingly difficult, for we found to our cost that we were being very badly hurt in at least two ways. One was that the new varieties of hard wheats were, in fact, far better wheats than the mellow ones, and that they were likely to oust the mellow wheats from the importing markets of the world. The other important trouble was, that even though the advantage of the new methods was more striking in the milling of hard wheats than in the milling of the mellow ones, and though it might be possible to prolong the commercial existence of the older mills if mellow wheats were obtainable, the new processes did actually produce better flour than the old ones from mellow wheats. There were in these conditions sufficient reasons for British hesitancy; but ultimately the superiority of modern methods asserted itself, and British millers saved their commercial existence by adopting them. Do not for one moment imagine that we liked the change. It was sheer necessity, not love of novelty, which drove us into spending the huge sums of money now locked up in plant, immensely greater than the amounts necessary for old-time milling. If we could to-day get anybody to buy the flour made from the wheats now available by millstone milling as it was practised forty years ago, we could afford to sell it at less money per sack—not more, as some of our food reformers would have you believe—for our working expenses, including interest on capital and depreciation, would be much less. But bear in mind that the bread made from such flour would not be the same article as that which our fathers ate, but something altogether different. I certainly should not like it, and I do not think the most ardent "food reformers" would. The principal point to be taken from this section of my paper is that the developments of modern milling have been caused largely by revolutionary changes in the origin and nature of our raw material. To illustrate the importance of this point I have brought here two pairs of loaves. To avoid complications, I have for the purpose of the comparison chosen wheats grown in England. One pair of loaves is made from a mixture of average English wheats, the other pair is made from Fife wheat grown for the fifth consecutive year in England. All the wheats were equally clean, but the Fife wheat was much harder than the others. One member of each pair was produced from millstone-made flour, the other from absolutely the same wheat made by roller milling. Even in this artificial light the difference in colour is striking, but to render the comparison more effective, I have, in accordance with a method I have used for a great many years, reduced to marks my opinion of their respective colours. The scale is arbitrary, but quite sufficiently accurate. The flour made by roller milling from average English earned 58 marks, the flour made by roller milling from English-grown Fife earned 80 marks, but whereas the millstone-made average English fell to 35 marks, a difference of 23 marks, the millstone-made Fife fell to 25, a difference of 55.

Wheat Cleaning.

One great development arising out of this change in our raw material was the absolute necessity for more efficient wheat-cleaning.

The English farmer of olden time, when the price of wheat was high, prided himself on the cleanliness of the corn he sold. Almost all the cleaning this wheat received before it was ground was carried out in the barn; the miller oftentimes did not think it necessary to clean it at all, but as prices fell, labour became relatively dear, and machinery was used in harvesting, so even English wheat began to contain some seeds, dirt, and stones. Foreign wheat always was relatively dirty, but with the advent of the new sources of supply we had to deal with an increased proportion of strange admixtures such as barley, oats, pulse, seeds of innumerable varieties, dirt, stones, excrement of vermin, &c. To extract such impurities much ingenuity and expenditure of capital for plant were necessary. Our mills to-day contain more machinery used for the purpose of wheat-cleaning only, than our fathers used in the complete processes of milling. I do not propose to

FIG. 1.

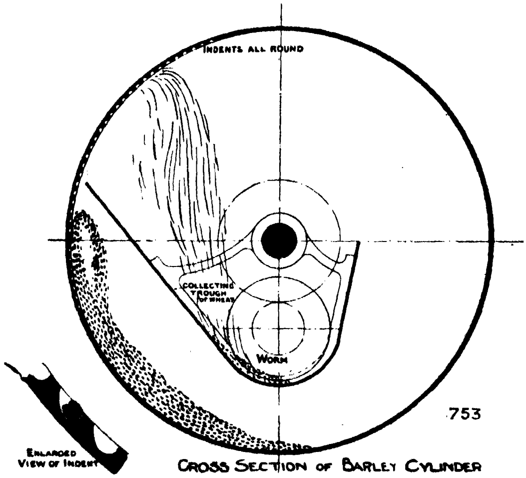


give you detailed descriptions of any of our machines, but to indicate briefly the principles upon which they work. Let it be understood throughout the remainder of this paper that the sizes of the various machines vary in accordance with the amount and character of the work required of them, and that different makers apply the principles involved in different ways.

The cardinal principles employed in wheat-cleaning are separation by size, separation by specific gravity, the use of attrition, and washing. Separation by size is applied in several ways. The simplest form is the use of a vibrating sieve. The separating medium is perforated metal, and the perforations are of various sizes according to the separation desired. For instance, if the impurities to be removed are larger than the wheat, the perforations would be of a size designed to let the wheat pass through them, and to carry away to a proper receptacle beans, peas, lumps of dirt, sticks, stones, &c., of large size; or if, for instance, sand and small-sized impurities are to be removed, the perforations would be small, so that the wheat will pass over them and the small impurities drop through them. Fig. 1 shows some grains of wheat photographed alongside two specimens of perforated metal.

This simple form of separation is used for preliminary treatment of the wheat; it is not sufficiently precise for difficult work. For instance, if small seeds are to be removed, a device far better than the sieve is a hollow cylinder made of zinc. On its inner side

FIG. 2.



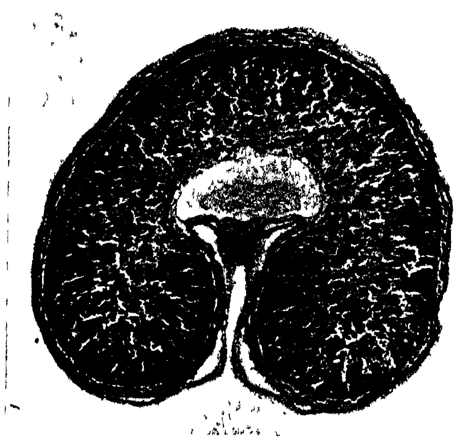
round indentations have been made. These indentations will receive the seeds, but are not large enough to take the wheat. The cylinder revolves slowly and the seeds fall of their own gravity into a channel placed inside the cylinder when in the course of a revolution the seeds in the indentations have been lifted high enough.

To remove such impurities as barley and oats from wheat, cylinders are used, but the application of the principle of separation by size differs from that just referred to. The seeds were smaller than the wheat, so the indentations were small. Oats, barley, and similar impurities are longer in the berry than wheat, so the indentations are made just large enough to receive the wheat, and small enough to exclude the longer berried impurities, and whereas small seeds were taken away from the wheat, in the case in hand, the wheat is taken away from the longer berried impurities. The illustration (Fig. 2) represents the cross section of such a cylinder.

Attrition is applied by passing wheat into a cylinder clothed wholly or in part with a finely perforated cover. Inside this cylinder metal beaters revolve at a great speed, and cause the grains of wheat to be rubbed with violence against themselves and the cover. This process is known technically as scouring.

The principal object is to remove adherent dirt and to break up lumps of dirt, or smut balls. If our fathers forty years ago cleaned wheat at all, the cleaning almost always took the form of separations by the use of sieves and of a form of scouring, both very imperfect methods. Scouring is still largely used as a part of our later methods, but there are two great

FIG 3.

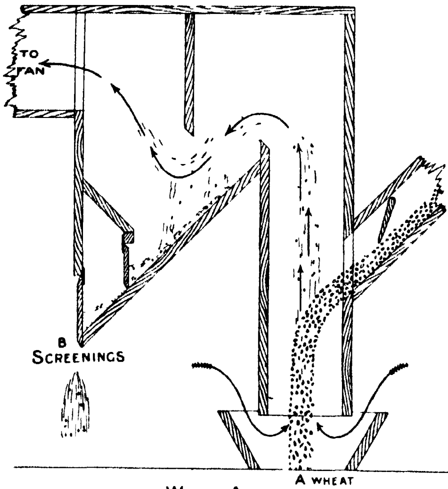


PHOTOMICROGRAPH OF A GRAIN OF WHEAT MADE BY MR. A. D. HALL.

objections to it, one that its object can generally be attained by the use of far less friction, and the other that it can never free wheat from dirt and dust owing to the peculiar shape of the berry. A glance at the illustration (Fig. 3) will show what I mean. The section was stained to bring into view the proteids, so the general dark colouration inside the endosperm cells represents proteid matter, the round dark specks the nuclei, which are very well defined because the section was cut from a partially ripe grain. The square-looking aleurone cells show up particularly well in this illustration.

Barley has no crease, that is to say no recess in its circumference, so it can be cleaned by a scourer such as I have described, but the possession of a crease is fatal to the attainment of that object in the case of wheat. You will notice that the crease of the grain of wheat in the illustration goes almost through the berry to such an extent that about one-third of the husk is situated in it. A large proportion of dust and dirt can lie in the recess so formed, out of the reach of the severest scouring. Having regard to the fact that in the old processes of milling, the crease was never effectually cleaned, it is not difficult for a miller to believe in the proverb which suggested that each person had to eat a peck of dirt in his lifetime. Modern milling has changed that state of affairs, as I will show directly. We retain the use of attrition in two main forms. One is in essence, the same as that practiced

FIG 4.



WHEAT ASPIRATOR 754

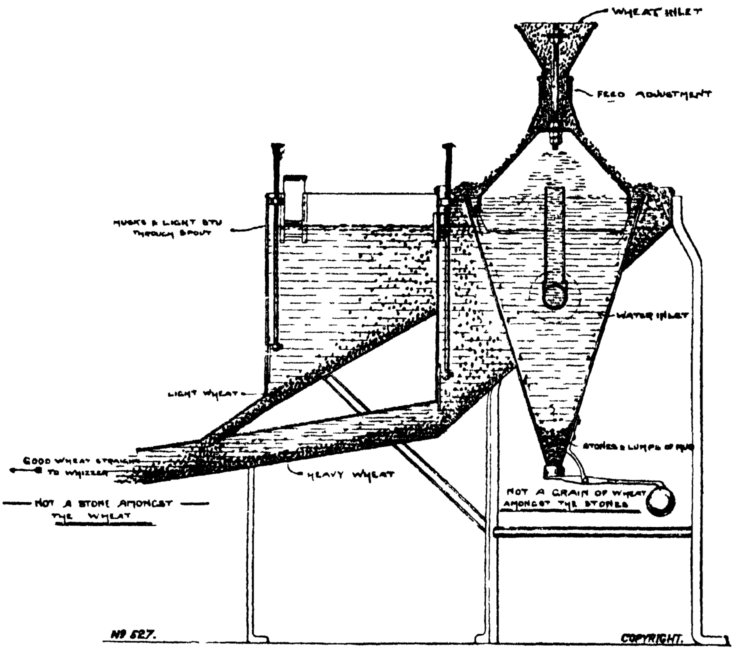
by our fathers, a form which is useful under some conditions. In the other form attrition is applied by the use of brushes, and that is most decidedly useful in the final stages of wheat cleaning, to take away impurities loosened by the earlier processes and by washing, but not completely removed. In some brush machines the wheat is passed between successive pairs of brushes, in others they take the place of metal beaters used in scourers and brush the wheat as it passes through the space between the revolving brushes and the stationary cylinder.

The principle of separation by specific gravity is very old indeed, and the use of wind for the purpose reminds one of the Psalmist. We separate chaff from wheat even now-a-days by wind, and use wind currents to separate other impurities from wheat in which the differences in specific gravity are far less than those between chaff and wheat. For instance,

to get away light shrivelled corn, small or light oats, small or light barley and light seeds, or, to state the point with more precision, to remove any extraneous matter whose specific gravity, as distinct from mere size, is less than wheat, we pass the feed down or through properly constructed passages, up or through which air currents capable of precise regulation are passed. These air currents carry away in them from the wheat the particles or substances of light specific gravity, including dust, and deposit them in separate places provided for them. Fig. 4 shows, in a simple form, the application of the principle.

An upward current of water is provided, the intensity of which can be regulated. On to this ascending current of water, the wheat containing stones is fed in an even stream. The water carries the wheat over with it into a machine called a whizzer, the stones drop through the ascending current of water into a place prepared for their reception. Another reason why water is used for this purpose instead of wind currents, is that the same operation, or substantially the same operation, washes the wheat. The crease to which I have particularly referred gets cleaned, lumps of dirt are dissolved, and the spores of bunt are

FIG. 5.



The strength of the air currents depends on the type, size, and speed of fan used, upon the use of regulating valves and other technical details. Sometimes air currents are used for separating stones from wheat, and in that case, as the specific gravity of stones is greater than that of wheat, the currents have to be just strong enough to carry away the wheat, and leave the stones behind. This method of extracting stones is not now in general use, because it was found that they could be extracted with greater ease and certainty, by the use of water.

WHEAT WASHING.

Such a stoner, of simple construction, is shown in this illustration (Fig. 5).

removed. The greater whiteness of modern flour is to a large extent due to the invention of this washing process. No doubt if it had been invented in millstone days, the flour made by that method of grinding would have been better than it was, but highly important though it is, it is not the only cause for our improved flours as we shall shortly see. The point to be taken at the moment is that stones, pieces of brick and such impurities are extracted through their differences from wheat as to specific gravity. Extremely dirty wheats, such as Indians, which have contained from 2 to 8 per cent. of absolute dirt, require a longer immersion or two washings. The wheat having been stoned and washed is separated

from the water rapidly by centrifugal action, generally by beaters working inside a perforated case, and then passed into drying machines. The wheat is made to pass through them in continuous streams, and currents of hot air and then cold air are blown through it, until it is dried sufficiently. This implies that wheats are not all dried alike, and that is true. Some wheats contain originally too much moisture, and therefore we have to reduce it; others are too dry to yield the best results either in a mill or in the bakehouse, so we intentionally let a few wheats absorb some water. If the miller grinds a mixture of very hard wheats and very soft wheats, the particles of flour produced retain to a large extent and for a considerable time the differences in nature which characterised the wheats from which they were produced, and to secure the best possible results in the bakehouse the particles of flour should be as nearly alike as to size and hardness as possible. The cattle feeder also demands that the offal should be not only good but of good appearance. This equalising of the condition of wheats has become an important part of a miller's education, and upon its efficiency depends to a large extent the perfection of the separation of kernel from husk, the ease or difficulty of making it, and the quality of the goods produced.

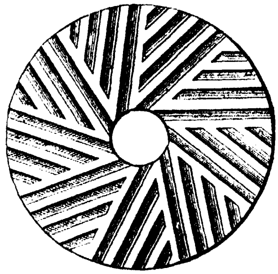
The number of machines used for wheat-cleaning in a mill equipped on modern lines would depend on the class of wheats ordinarily used, and on the quantity of wheat milled, but some idea of the amount of work involved in wheat-cleaning may be gathered from the fact that wheat has to pass through from six to ten separations by size on successive sieves; through from six to ten separations according to specific gravity by wind currents; through, say, two scourings or brushings; and through one, sometimes two, washings and dryings. To extract stray pieces of metal, such as nails and wire, the wheat is passed over magnets, which retain such metallic impurities.

Grinding.

I must not dwell any longer on the important processes of wheat-cleaning, but pass on to the processes of grinding and the separation of husk from kernel. It is obvious that considerable force has to be applied in grinding; but a great underlying principle of modern milling is the reduction of the amount and intensity of the friction used in grinding. To those of you who know the great number of rolls employed in a modern mill, and the number of successive grindings to which the wheat and its component parts are subjected nowadays, and who recollect that thirty years ago it was the aim of millers to effect the complete reduction of wheat in one passage between millstones, this statement of mine as to the diminution of friction may seem paradoxical, and it is necessary for several reasons to establish the truth of my statement.

I am just old enough to have worked in the millstone era, and shall always entertain the millstone miller's affection for that fine implement. It was no upstart, but, on the contrary, the quintessence of the experience and knowledge of very many generations of capable millers. Millstone building was a recognised trade of specialists, and the stone-man was a skilled man of high standing in the mills of those days. For the grinding

Fig. 6.

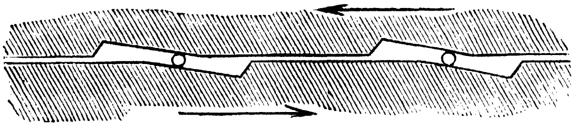


of wheat, millstones made of a special form of stone were used, found in comparatively small layers in various parts of France. It was known as French burr, and was a form of flint, practically pure silica. No great quantity of it existed, but even so there were several subdivisions of it according to quality. The best millstones were built of many pieces of burr, selected for quality in the general sense, and, in particular, for their different characteristics according to their position in the finished implement and the work required of it.

When finished, millstones were circular and worked in pairs, usually in a horizontal position, and provision was made for ensuring not only a standing balance but a running one also. As a rule, the under one was stationary, the upper one, weighing from 10 to 15 cwt., was usually suspended on one central point and revolved at a rate of 120 to 140 revolutions per minute. Their surfaces, more particularly near the circumference, had to be kept in a practically perfect plane, for the relatively ponderous upper stone had to run so near the

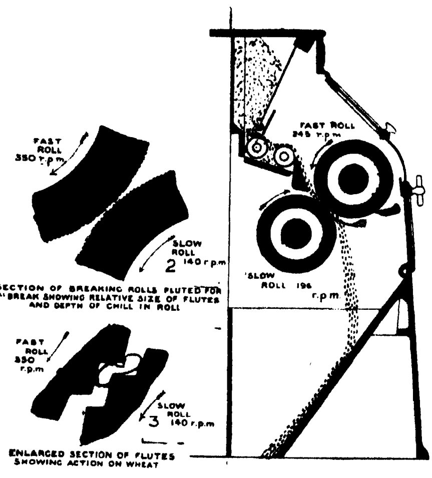
bedstone without touching it at any point that the husk of the wheat, in thickness of almost infinitesimal measurement, had to be touched on both sides by the stones without being unduly pulverised. In Fig. 7, the stones are not shown so closely together as they would be in working. It is obvious that to obtain high-class work the trueing of the face and all the adjustments had to be of the highest class. No one ever discovered the course of the grains of wheat between the stones, but this is certain that as the stones were usually four feet in diameter, the wheat in one passage between them, would be subjected to at least four feet of rough rubbing between flinty surfaces, involving necessarily, in spite of all precautions, the use of friction in an intense form. Very many skilful devices were adopted to minimise this friction, but but nothing that was done cured the inherent vice, rendered doubly vicious when brittle wheats were introduced, of excessive and unnecessary friction employed in grinding.

Fig. 7.



Section of Runner and Bedstone Face.

Fig. 8.



751 Half Cross Section of Diagonal Four Roll Mill with Reducing Rolls

Compare that with our modern methods of grinding by rolls (Fig. 8). They are made of chilled iron, and are usually but not invariably 10 inches in diameter, and of varying lengths according to capacity, from say 20 to 60 inches. For what we call break work, that is to say for the preliminary work of removing bran, the largest sized offal, from the broken kernel, they are corrugated in a way not unlike the teeth of a saw. To get a commercially complete separation of broken kernel from the bran, the wheat is passed through successive breaks. In the early days of roller milling these successive breaks were usually six in number, but to-day there are generally four. For the first break the corrugations of each roll are say 10 to 13 per inch of roll surface, and the two rolls are kept sufficiently far apart to break down the grains of wheat to say half or quarter their original size. For the last break the corrugations would be say 26 per inch, and the two rolls are made to run closely enough together to free the bran entirely of kernel according to commercial standards. The second and third breaks are intermediate as to their corrugations and adjustments. For each break both rolls revolve with usually a differential speed of 2½ to 1. Sometimes the two rolls are placed horizontally, sometimes vertically or practically so, but according to the latest development, or redevelopment on this technical point, they are placed diagonally one to the other. The object is to present the stock to the rolls in a perfectly even stream. For the purposes of comparison with the millstone, the essential points to be remembered are that the rolls are perfectly round, so that the whole of the grinding is done by one nip at the point of contact. Another essential point to be borne in mind is that at the point of contact the two rolls are moving in the same direction though at different speeds, so that the violence of the friction on the wheat is minimised as compared with the extreme violence of the friction applied by the two millstones, one stationary, the other revolving at a periphery speed of say 1,600 feet per minute. Still another essential point is that the minimised friction of the roller mill is applied at four successive operations in

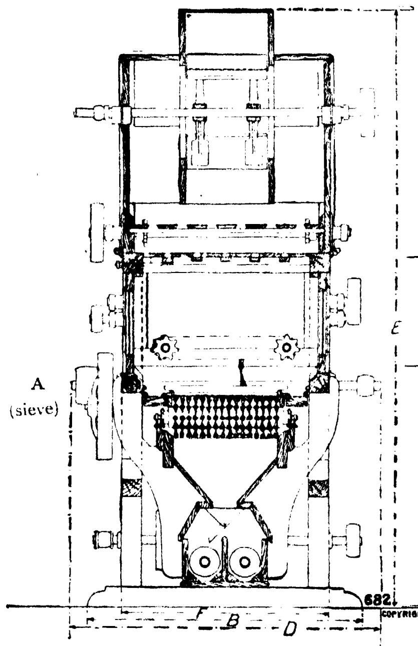
gradually increasing intensity, and that between each break those parts of the kernel which have been loosened and sufficiently broken down are removed by what we call "scalping" for further treatment separately.

The next principle to be noted is this. In our old methods we sought to make as much flour as possible at the first grinding, we now seek to make as little as possible in the breaks, that part of our processes which I have just been briefly describing. We cannot help making some flour there and that is removed as quickly as possible, but our real object is to obtain the kernel in a granular form, because we can thereby obtain a more perfect separation of husk from kernel.

Purification.

This brings me to the process known technically as purification. In essence it is an application of the principles of separation according to specific gravity. Given any number of particles of the same size obtained from the same wheat, their specific gravity will vary according to their quality, and indicate with sufficient accuracy the amount of grinding required to resolve them into finished flour and finished offal. In purification we apply wind currents capable of fine adjustment to this separation. Theoretically separations in this way might be applied to particles of any size, in practice owing to the difficulties of applying them to very small ones we make no attempt to apply purification in this technical sense to flour or to stock which will pass through the dressing medium made of silk possessing 13,000 holes to the square inch, but the particles which are larger than that up to those which will pass through a dressing medium, technically called a cover, containing 324 meshes to the square inch (18 to the lineal inch) are all purified. To ensure good work we have to grade carefully acccording to size, that is to say we remove all such fine particles as I have mentioned, and divide the larger ones up into various grades according to size, so that no one machine called a purifier has to handle particles varying greatly in size. These grades are known technically as semolinas, coarse or fine, and middlings, coarse or fine. The latter must not be confounded with the offal known in some districts by the same name. At various periods wind currents have been applied in various ways, but at present the almost invariable practice in Great Britain is to use them in combination with a sieve. The sieve, usually about 8 feet long and say 16 to 24 inches wide, is made to vibrate 450 to 500 times per minute. Its mechanical adjustments have to be fine and precise, so as to ensure a perfectly level, even, continuous flow of the stock over its surface. The cover of the sieve is usually made of silk, and its meshes vary in each section of the machine according to the stock to be purified, so that if the wind currents were shut off, the stock would be still sorted, according to size, in successive sections of the machine, and none of it would or should pass over the tail end of the sieve.

Fig. 9.



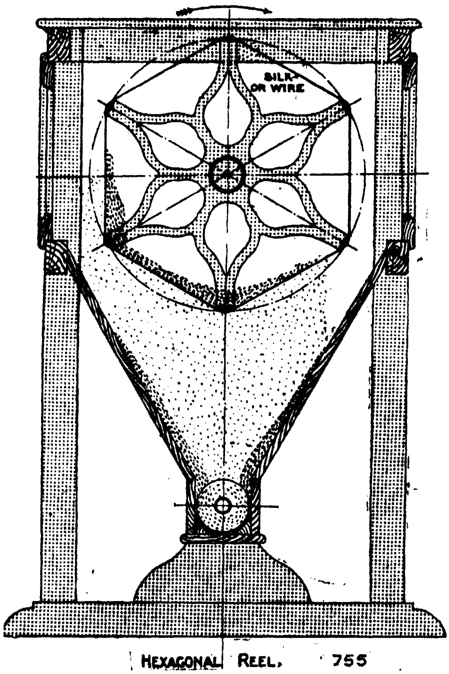
Each sieve is furnished with a fan, which draws air currents through the stock passing down the sieve. The lightest particles, finished offal, are taken up and deposited by themselves at B; particles of high specific gravity are not lifted by the wind currents, but pass through the cover to be reduced on smooth rolls. Particles of intermediate specific gravity are sorted out, and are either lifted on to trays placed immediately above the sieve at C, or carried over the tail end of the sieve, either into a receptacle for finished offal, or passed to rolls placed later in the process of grinding.

Flow Sheet.

This brings me back to rolls again, this time to machines similar in most respects to the

break rolls, but smooth in their grinding faces, and running at a lesser differential. In a large mill there may be hundreds of machines and mechanical appliances, but they are mutually inter-dependent, and form in essence one large machine, each unit essential to the whole. A drawing setting out their relation, one to the other, is called a flow sheet, and it takes a very clever miller to design a good one, that is to say in effect a mill capable of doing throughout the very best work required of it. I cannot therefore pretend to explain even to this educated audience the extremely com-

FIG. 10.

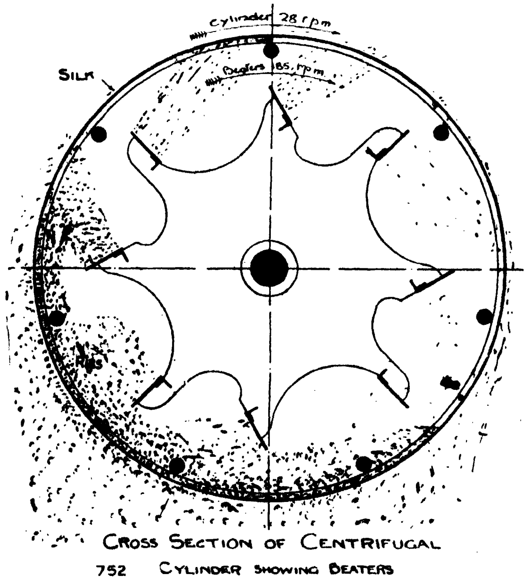


plicated flow of the stock through a modern mill. Suffice it to say that the many various divisions and subdivisions of stock according to size and specific gravity, receive after purification differing treatments. Some stock can be resolved into finished flour and finished offal by one grinding and dressing, others will get as many as seven. The essential principles are that each stock shall get sufficient grinding and no more, and that immediately it is resolved into finished product it shall be passed out of the processes altogether.

SCALPING AND DRESSING.

I have just spoken of grinding and purification. Incidentally I mentioned scalping and dressing. In these two processes, the same principle is applied, separation according to size. Scalping deals with coarser stocks, such as broken wheats in various stages of grinding, dressing in the technical sense is generally confined to the separation of finished flour from various stocks. After each grinding, the material ground is passed either to scalpers or dressers. The machines used are either reels, centrifugals, or plansifters. The reels are generally either circular or hexagonal (Fig. 10). A frame-work carrying the dressing medium or cover revolves at, say, 28 revolutions per minute. The slope of the machine causes the larger particles of the stock to pass longitudinally down the reel and over its tail

FIG. 11.



for subsequent treatment; the particles small enough to pass through the cover are carried off to a separate destination. The stock inside the reel rolls about the inner surface of the cover, or is lifted by the revolving of the machine and falls of its own gravity on to a fresh part of the cover. In a centrifugal, as it is called, centrifugal force is applied (Fig. 11).

That is to say, inside a round or hexagonal cylinder covered with wire or silk are beaters carried on arms fixed on a central shaft. Both the cylinder and the beaters revolve in the same direction, the former at, say, 28 revolutions per minute, the beaters at about 185. The amount of the centrifugal force applied by the beaters in this way is not nearly so severe as it may appear to be for two reasons. One is the

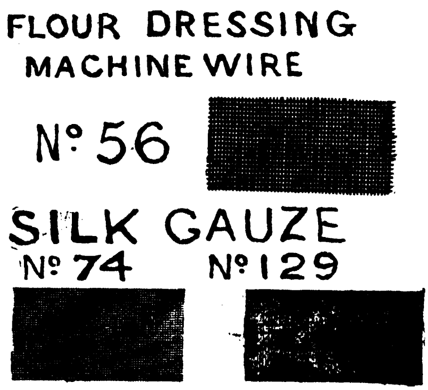
shape of the beaters, which are prevented from throwing the stock at right angles against the cover, the other because there is a clear space between the outside edge of the beaters and the cylinder. This means that the heavier particles are thrown against the cover with more force than particles of the same size of less specific gravity. This point is often overlooked in technical arguments, but it is a very real one, which can be proved by sifting the overtails of a centrifugal handling poor stock over a sieve covered with silk of the same mesh as the centrifugal itself is using, or even if the testing sieve be clothed rather more finely. The overtails contain particles of the same size as the flour which has passed through the cover of the centrifugal, but they are altogether inferior in quality.

Plansifters are in effect a number of sieves placed one above the other in a series and operated mechanically. They seek to reproduce as nearly as may be the effect of skilful hand-sifting, and theoretically there is a great deal to be said in their favour. They are largely used on the Continent and in America, and some firms of high repute use them in Great Britain, but speaking generally they have been discarded, after exhaustive trials, in the United Kingdom. Perhaps the sudden and many variations of our climate, or the variations of the wheats we have to use, are the cause of that, but whatever may be the cause our millers strongly prefer the more reliable and in practice simpler forms of dressing represented by the centrifugal.

For scalping it is possible to use with advantage an inclined plane set longtitudinally at varying angles, so that the stock to be scalped can fall, or, to be precise, can roll of its own gravity over the face of the cover. This is a recent application or reapplication of the all-pervading principle, the reduction of harmful friction to a minimum. We are constantly getting more or less successful attempts to do away with friction in handling.

The covers of these scalping and dressing machines are made either of wire or silk. Thirty years ago, wire or a cloth made of worsted, was almost exclusively used, and the meshes per lineal inch did not in common practice exceed 70, frequently did not exceed 56. This represents coarse dressing, and so long as the wheats used were mellow and approximately alike in their degree of hardness or mellowness it answered well enough. But when we began to get the harder wheats I have referred to, two important considerations came into effect. First the colour of the flour and bread went down, and that not only meant dark bread, but worse flavoured bread. Flour containing a lot of powdered husk is not nicer in flavour, but quite the reverse. Furthermore the baker found that his fermentations were prejudicially affected by the irregularities in texture of the flours made from a mixture of hard and soft wheats, and a further way to minimise such irregularities was to dress the flour more finely. For by any method of grinding a large proportion of fine particles is sure to be made. So as a first stage, even before rolls were introduced, millers began to use silk for dressing because it was possible with its very fine and strong threads to weave covers of far finer mesh. Makers of wire have now dis-

FIG. 12.



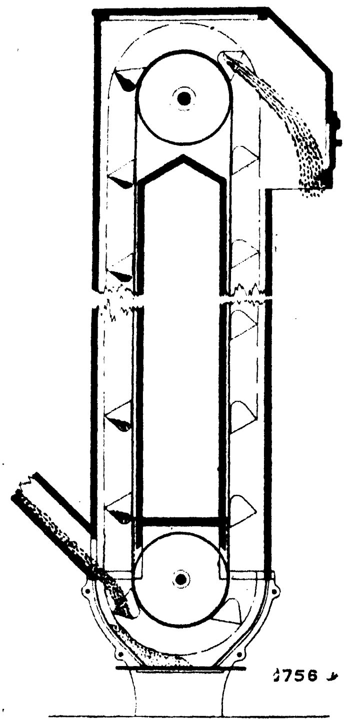
covered the way to make covers of extreme fineness of mesh, but practically all fine separations are made with silk manufactured mostly in certain districts of Switzerland. The finest numbers in ordinary use contain say 150 threads per lineal inch, or say with 22,500 holes per square inch. The illustration on the screen (Fig. 12) represents photographs of three pieces, each half an inch in height, of material used as dressing mediums. The one marked 56 is of wire, and represents, counting vertically, 28 meshes in the half-inch, a size of mesh commonly used thirty years or so ago. The one marked 74 is known commercially as No. 6 standard silk, and, counting vertically, there are 37 meshes in the half-inch photographed. This represents now exceedingly coarse dressing. The one marked 129 is known commercially as No. 13 standard silk, and that half-inch contains, say, 65 meshes, which represents fine—but not very fine—dressing according to modern practice. Here let me correct one false idea commonly

held by "food reformers." The highest-grade figures are not the most finely dressed according to modern practice. They are made from the semolinas and middlings, which are of the highest specific gravity and freest from husk. There is, therefore, no necessity for very fine dressing, and, as a matter of fact, the highest-grade flours as a class have been subjected to less grinding and are probably the most coarsely dressed flours made in a mill. It is the darker ones, call them "seconds" quality if you like, for which exceedingly fine dressing is used.

Of course, if fine dressing be used, more grinding has to be done, for the kernel has to be reduced to smaller-sized particles; but even then my point as to friction used in grinding holds good, for it must be remembered that rolls grind only at the point of contact, that the reduction rolls are smooth, and run at a small differential only, so their action is more nearly related to crushing than to grinding. Thus I come back to my great points, that in spite of a lengthened and a much more complicated process the most important principles lying at the root of modern milling are first and foremost, an immensely improved system of wheat-cleaning, and thereafter the use of far less friction in grinding, less in amount and far less in intensity.

One great change resulting from the adoption of modern methods is that modern mill buildings are altogether superior to old ones. They are not only larger in area, but possess higher floors, are better lighted and are altogether cleaner. Wheat cleaning is at best a dirty job, and in our modern mills it is carried on in separate or practically separate buildings, but our subsequent processes are carried on under incomparably better conditions than old time milling. From the time that wheat reaches the mill-warehouse until the products derived from it are delivered at the other end of the processes as finished articles ready for sale, they are not touched by hand. I have already said that directly any part of the wheat is resolved into finished flour or finished offal it should be removed from the processes, and as a consequence some of our products get very little milling, but that small proportion which has to pass through the whole length of our processes, travels a considerable distance, and is lifted from bottom to top of the mill many times. With the object of avoiding as far as possible the movement of stock by mechanical means, modern mills are high and

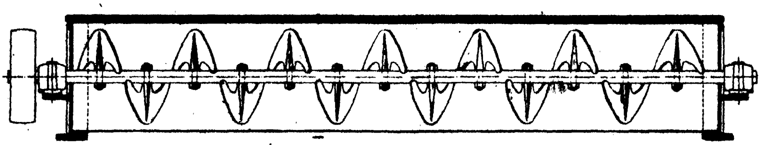
FIG. 13.



ELEVATOR

have high floors, so that stock can fall from floor to floor, and machine to machine in sequence, by its own gravity. The two implements most frequently used in the mill itself for moving stock automatically, are the elevator and the worm. The former is a travelling band, carrying cups which lift stock vertically, the worm is simply some form of archimedian screw, generally used for moving stock horizontally or upwards at a slight angle. We use other mechanical means

FIG. 14.



PADDLE WORM CONVEYOR

for moving stock about, but the illustration of the elevator and worm, gives a sufficient indication of the principal implements employed in such work (Figs. 13, 14).

BLEACHING.

I cannot omit from a description of modern developments of flour-milling a reference to bleaching. In some parts of the United Kingdom consumers demand a very white flour, and that demand cannot be satisfied by using wheats containing a high percentage of starch, because their correspondingly low percentage of nitrogen unfits them for the production of the highest qualities of flour. Furthermore many starchy wheats yield flours which are not white but yellow. This characteristic is not confined to wheats of the *durum* type, for many of the *triticum vulgare* genus possess it also. This extreme yellowness diminishes as the flour gets older. In some way or another Nature bleaches it to a very appreciable extent. Millers who bleach, seek to do within two or three minutes as part of the milling process, that which Nature does in several months. Bleaching, as its name simplies, whitens flour, but another important effect must be mentioned. Indeed M. Frichot, one of the earliest inventors in this field, seemed to regard the sterilising of the flour as more important than the whitening. His argument was that pure endosperm contains no active ferments, that these ferments which do harm to the flour, come from the aleurone cells and the germ. To produce flour containing a minimum percentage of these harmful ferments French millers extracted only a low percentage of flour from the wheats they used, allowing the aleurone cells to go into the offal, but if they could sterilize the flour and so destroy these ferments, they could extract from their wheats a much higher percentage of flour by putting into it the aleurone cells which contain a very high percentage of nitrogenous bodies. In that way he said they would obtain a flour of higher nutritive value, make a larger proportion of the wheat available for human food, and by a subsidiary but coincident result, whiten the product and make it suitable for those consumers who demand very white bread. I believe this is a fair summary of his arguments, and though I myself do not wish to express an opinion on them, or say that his premises correctly represent the practice of British millers, the point of view expressed and the effect claimed therein must be kept in mind when the question of bleaching is considered. The process is used to only a moderate extent in Great Britain. British millers hold sharply divided opinions as to its merits and demerits. As yet it is only in its infancy or adolescence, and inventors, millers, chemists, and electricians are far from being in agreement as to the actual bleaching agent or its operation. I am not concerned commercially, directly or indirectly, in any bleaching process, so can regard it as an interested outsider. One mechanical detail is common to all bleaching processes. The flour is kept loosely in motion inside a cylinder, and into that cylinder the bleaching agent is blown. In some processes this bleaching agent is a gas obtained by the action of chemicals, but the best known processes employ air blown or drawn through some form of electrical discharge, silent, sparking, or flaming. I am not a chemist or electrician, and will not venture to say what it is which gives to that air its power to bleach. It may be ozone or oxides of nitrogen. Around that innocent-looking problem a considerable controversy rages. Authorities are not agreed on the points whether it is the ozone present that bleaches or which cannot bleach, or whether it be peroxide of nitrogen which does the work, or which imparts to the ozone, existing side by side with it, the power to do so. Furthermore, the controversy does not end there, for it has not as yet been ascertained with precision how the flour is affected. The weight of any flour passed through the process is not appreciably altered, so that the bleaching would appear to be due to a change in the appearance of some constituent, or constituents. Here also I can express no opinion, for authorities differ as to whether it is due to oxidation or not, and as to whether the actual bleaching is caused by the decoloration of the fatty matter itself, or whether through the fatty matter being rendered transparent the white colour of the starch is more apparent to the observer. It seems to be agreed that the effect is due to some change wrought on the fatty matters. Millers who use the process at all seem, according to most recent practice, to bleach to a very moderate extent only, or to restrict its use to the flours produced from wheats with very yellow endosperms. Air containing one part in 13,000 of ozone and one part in 40,000 of oxides of nitrogen, principally peroxide, will bleach perfectly according to most recent ideas. There is nothing nasty in the process itself, or in the

flavour of the bread produced from properly bleached flour. Bleaching certainly makes flour whiter—that is to say, white according to the precise signification of the term, the hue of chalk not of cream—a point which does not appeal to many first-class millers and bakers; it seems to improve the keeping qualities of flour, and inventors of the highest standing claim that in some unexplained manner flour when bleached will make more bread than it will do in its untreated condition.

Dietetic Value.

The question may now be asked, are these modern developments of flour-milling harmful to the consumer? No one, we may be sure, will object to the improvements in wheat-cleaning, so that a large proportion of our modern developments can most assuredly be esteemed wholly good. The controversy will centre round the all-pervading endeavour of the modern miller to produce flour as free from husk as possible. That is, apart from improved wheat-cleaning, the great line of advance from our point of view. I will speak of the relative food values of whole-meal bread and white bread, because upon those I propose to base an important argument bearing upon the point at issue, but whole-meal bread was not thirty years ago, is not now, and is not likely to be, an article of diet used to any great or even appreciable extent. Basing an opinion upon the amount of trade done by millers in wheat meals, I do not think that whole-meal breads represent more than 2 per cent., perhaps only 1 to 1½ per cent., of the total bread consumed in England, in spite of the long-continued campaign of food reformers in its favour. The human digestive apparatus seems to rebel against its use as a regular article of diet, pleasant though it is as an occasional variation on white bread, and useful though it may be to those who, from constitutional or acquired infirmity, require a mild irritant to bring about improved peristaltic action. The best market in the United Kingdom for the highest grades of flour is not London, but the mining and manufacturing districts of South Wales and the North, where great physical exertions are made by the consumers.

There are several points to be considered in connection with this question of dietetic value. Let me take a very few important ones. First of all, consider the function of the husk in the economy of Nature. Man has a multitude of things from which to choose his articles of diet. Nature, so far as wheat is concerned, is, it is fair to say, far more anxious to perpetuate the species than to care whether man eats the whole berry or only 70 per cent. of it. Wheat is a particularly hardy plant. We sow it when the conditions of climate and soil are unfavourable to the existence of delicate seeds, in wet, cold ground. The germ, say 1½ per cent. of the whole berry, is the source from which the young plant originates; the endosperm, call it the flour if you please to do so, is the food of the baby plant until it is old enough and strong enough to get its sustenance from soil and air. The husk is the cover provided by Nature to protect the food of the baby plant in surroundings unfavourable to its preservation. So we find this protecting cover constituted largely of woody fibre, able to resist disintegration; in other words relatively indigestible. I noticed a few days ago in examining wheat which had been planted about six weeks ago and had grown several inches long above ground, that attached to each plant was the husk only of the seed, the endosperm appeared to have been quite consumed by the growth of the plant, but the husk in every case I examined was practically intact. We need have no hesitation in discarding it for human food. Give it as we do to animals, say to the cow which chews its cud, and take back for our own consumption a large part of the nutriment it contains as milk and beef.

Take another point. The average consumer finds wheatmeal bread more or less unpalatable, yet the wheatmeal of commerce is made from picked wheats. British millers get very few wheats from which saleable wheatmeal can be made. Those we use are chosen largely because of their excellent flavour. The average wheats we use for flour-making would not make the whole-meal breads of commerce but something of relatively very poor flavour. Do not gather from that statement that our ordinary wheats are inferior in food value to those used for wheatmeal. The latter contain, as a class, less nitrogen than those from which white bread is made.

Another point is worth noting. Nearly all the brown breads of commerce are baked in tins, and this implies that they contain more water than average white breads, and water should be cheap, but in those cases it is not so.

These matters have a bearing on the questions at issue, but are not, as I have already said, the real points themselves; for the comparison to be made is not between wheat-meal and white flour, but between millstone-made

flour and roller-made flour. The latter contains less husk than the former, and you may not improperly think that it is a substantially different case to the one concerning whole meal.

The first consideration to be borne in mind is, or at least should be, an obvious one. Samples taken at haphazard of millstone-made and roller-made flours, may be perfectly fair specimens of their respective kinds, but they cannot be used as illustrations of the effects of the respective processes, unless the same wheats be used in both cases. There are many hundreds of varieties of wheat, and each variety can be more or less affected by an enormous number of variations in natural conditions, such as climate, soil, water supply, &c. I must confess that the literature on the points involved seems to be a maze. I will attempt to reduce the problem to a simple form, and the first great simplifier is the condition just mentioned.

Let me interpose these facts. The wheats we grind nowadays contain more nitrogen than those in common use thirty years ago. The increased whiteness of modern bread is not due to the use of more starchy wheats. Those starchy wheats, as we have already seen, do not invariably make white-looking flours, and anyhow it is impossible to make bread of the highest quality from those wheats only, which contain a high proportion of starch. You may have noticed that the bread made from average English wheat was substantially darker than that made from Fife wheat, even though both were roller made, yet the flour itself from the average English was much whiter in appearance than the Fife flour. It was lack of strength, in other words and with sufficient accuracy, its lack of nitrogen, which accounted for the relatively dark appearance of the average English in bread. If the two sorts were mixed with a substantial proportion of very strong flour in exactly the same proportions, the average English in the blend would yield bread quite as good in colour as the Fife in the blend. A relatively high nitrogen content is necessary for the production of the higher qualities of bread.

To get at the truth of the case, I milled the two types of wheat already referred to—the one mellow, the other hard—and sent the wheats, the flours produced therefrom, and loaves corresponding to those I have shown you, to my good friend, Mr. A. D. Hall, of Rothamsted, with whom I have had the pleasure of collaborating in other matters for some years. He has very kindly analysed the complete set for me, and you will see in the published reports of these proceedings the analyses he has sent me. The results are more favourable to modern milling than I anticipated. You may have gathered already that the millstone-made flour from the mellow wheat contained less powdered husk than the flour made from the harder wheats by millstones. Mr. Hall's analyses show that the flour made by rolls from the mellow wheat contains quite as much nitrogen as the flour made by millstones from the same wheat, but that in the case of the hard wheat, the millstone-made flour contained more nitrogen than the roller-made. That arises from the larger proportion of powdered husk which the former contains. In modern milling we frequently separate the different qualities of flour made from one and the same wheat, into at least two grades known in Great Britain generically as "patents" and "bakers." The former is much better in colour, loosely called whiter, than the "bakers" grade. Here is a loaf made from the "patents" produced from the harder wheat of the two analysed. As I anticipated, it contains less nitrogen than the "bakers" grade, and substantially less than the wheat from which it was made, which may be taken to represent the analysis of wheat meal if the wheat in question had been converted into that product. It appears, therefore, that our modern processes have in some cases diminished the percentage of nitrogen in the white flours, particularly so in the higher grades of flour. If the chemist were the final arbiter in the matter, modern millers would have to admit that to that extent we are doing something to the detriment of the consumer. But let us get to grips. What have we done to bring about that result?

Germ.

Dealing with a small matter first, we have abstracted the germ more or less perfectly. I use the qualifying words because in extracting it we have rolled it three or four times and probably have passed some of it by abrasion, and some of its fatty matter by exudation into the flour. It is commonly believed that in the old processes germ was passed into the flour. We certainly did not extract it as a separate product, and because we did not see it, a good many believed it went there. But that is true to a moderate extent only. Germ retains its characteristic stickiness, due to the oil it contains, whatever process of milling be used and

as the millstones in spite of their relatively rough handling of wheat did nevertheless produce a large percentage of good bran, we have no real reason to think they ground up the germ so finely that it all went into the flour. If the intermediate product I referred to were treated separately, a substantial quantity of germ could be and actually in the later days of millstone milling was extracted, but besides that, a proportion of it then as now was inextricably mixed up with the finished offal and was disposed of in that way. It could be seen by a magnifying glass in the offal, but to put the matter beyond doubt I took a great amount of trouble to treat the finished offal obtained by millstone grinding from the harder wheat of the two milled and analysed, and here is a sample of practically pure germ obtained from it. Girard gave the percentage of germ contained in wheat as 1·46 per cent. say 1½ per cent. It contains a high percentage of nitrogen and fatty matter, and, *primâ facie*, its abstraction is a loss to the consumer. Millers extract it because it contains some active ferments which prejudicially affect flour. The War Office found that out for itself in South Africa, and one of our trade papers, *Milling*, of Liverpool, has put it on record that the military authorities abandoned buying lower grade flours for that campaign and bought patent flours only, because they kept so much better than the lower grades. The exact difference in the proportion of germ which found its way into flour in millstone days and that which finds its way there now has, so far as I know, never been ascertained. Millers extract about ½ per cent. as a separate product, and the remaining 1 per cent. finds its way into offal or into the lower grades of flour. Anyhow the difference between the nitrogen of wheat and the nitrogen of germ has to be divided by a large divisor to arrive at the infinitesimal harm done in theory to the average of the whole and the importance of this has again to be whittled down owing to the harm which the ferments in the germ may do to the flour if it be stored for any length of time.

Digestibility of Breads.

A point in the argument far more important than that concerning germ, is the one concerning the finely divided husk found in flours made by both processes, but of which there is a far larger proportion in millstone-made flour. To present the case in its simplest form, let me state it in this way, The highest grade flour produced by modern methods from any wheat is practically pure endosperm. We may with sufficient accuracy regard the analysis of such flour as that of the endosperm itself. The commercial grade of offal which is the nearest approach to pure husk is bran. It probably has attached to it a considerable proportion of the aleurone cells but that does not vitiate my argument. Between these two extremes are many grades or qualities of flour of which the main distinguishing feature is a diminishing commercial value, due to the fact that as the quality falls so the proportion of husk they contain increases. Clifford Richardson several years ago made analyses of 88 products including the wheat used, obtained from various parts of a roller process mill. In an appendix to the printed report you will see a few of his most important results. Dealing with proteids first I may now mention that the wheat contained 14·35 per cent., the patent flour 12·95 per cent., the bakers' grade 14·88 per cent., bran 16·28 per cent. of proteid matter. Of ash the wheat contained 1·79 per cent., the patent flour ·39 per cent., the bakers' grade ·62 per cent., the bran 5·59 per cent. The same sort of progression is to be noted in connection with the ether extract, and inversely with the carbohydrates. The argument becomes involved if we take into account the proportion and the chemical constitution of the aleurone cells, so I intentionally omit further reference to them. The moral I want to draw from these figures is that the highest percentages of proteid, ash, and ether extract, are to be found in the bran, the lowest in the highest grade flours. As the percentage of husk in the flour rises, so the percentages of the constituents I have just named rise also. If, therefore, the food value coincides with the percentages of these constituents ascertained by chemical analysis, then our modern methods of milling would in fact operate to the detriment of the consumer. But that is just where chemical analysis break down. It does not indicate the food value of these products, in other words the human digestive apparatus works on lines of its own which tell a different tale to that told by the chemist. British scientists have made laboratory experiments on the relative digestibility of various breads, and the results they have obtained agree in the main with the elaborate experiments I will now summarize.

The University of Minnesota, situated in one

of the great wheat-growing districts of the world, has made scores of experiments in this way. Various wheats have been taken, and from them, what we should call wholemeal, wholemeal less the largest pieces of bran, and white flour have been made. Men engaged at different kinds of labour, were induced to live for four days upon rations composed of milk, and the various breads made from these products. The foods taken, were weighed and analysed, the weights of the individuals noted, and their urine and fæces weighed and analysed. The fæces were examined microscopically also. The following sentence, adapted to our English nomenclature, gives the results of these trials. While wholemeal, and wholemeal minus the largest pieces of bran, contain more proteid and fat and have a "higher heat of combustion" they actually yield to the body because of their lower digestibility, smaller percentages of digestible nutrients and available energy than the white flour. These results were the same in every case. That seems to be conclusive as to the wholemeal breads; it does not exhaust the point at issue between millstone-made and roller-made flours. That has been dealt with also. Bran was finely pulverised and mixed with white flour and digestive experiments carried out as in the last-mentioned cases. The flour containing finely pulverised bran was more digestible than the coarsely granulated wholemeal, but less digestible than the white flour without the admixture. "When bran was finely pulverised it failed to digest as completely as the white flour and therefore the addition of bran lowered the food value of the flour." That seems to me to show that in excluding, so far as we can, husk from flour, we are not doing harm to the consumer but good.

I can only deal with one more point. We are told that white flour is the cause of bad teeth, because it contains relatively so little mineral constituents. That seems to me as unlikely as the statement that tomatoes are the cause of the increase of cancer. There have been very many other changes in our articles of diet. For instance, how about the large quantities of sugar consumed nowadays and the fact that so many infants do not now receive their natural food? The questions concerning the digestibility of ash are being dealt with in a similar way to that I have just described, and as yet the results are not known. I can, however, point out that it is contained principally in the husk, and if the human digestive apparatus fails to extract the other constituents from the husk we may reasonably anticipate that it would fail to extract the ash. Moreover, it is open to question whether the ash is in a form which can be assimilated by animals or human beings, and even if it should be so, it seems that white flour contains sufficient phosphates to meet all the demands of the human body. If that be so any additional amount supplied to the body would have to be excreted by the kidneys in a practically unchanged form. However that may be, a statement I came across in some American literature is interesting. The negro of the South lives upon a diet which contains far less phosphates than are found in white flour, yet the teeth of the negro are generally sound and white and do not show any lack of phosphates.

At any rate "I practice what I preach." For my own consumption I insist on having the best coloured bread obtainable, for I think it is the nicest, its appearance is a palpable guarantee of cleanliness, and I believe I am assimilating the greatest amount of nutriment obtainable from wheaten bread with the least possible strain on my digestive organs.

APPENDIX A.—Analyses made by A. D. Hall, M.A., at Rothamsted (December 1906).

	Per cent. nitrogen reckoned as proteid.	Per cent. nitrogen reckoned as proteid in dry bread.	Per cent. moisture in bread.
Average English grain	11·3	—	—
,, millstone-made flour	9·8	10·15	33·91
,, roller-made flour	9·9	10·01	32·80
Fife wheat, grown for the fifth consecutive year in England	12·7	—	—
,, millstone-made flour	12·7	12·9	34·00
,, roller-made flour	11·9	12·4	33·27
,, highest grade roller-made flour	11·6	11·7	37·35
Typical whole wheat meal	12·7	14·7	38·18

APPENDIX B.—ANALYSES BY CLIFFORD RICHARDSON.

(Extracted from Bulletin No. 13, issued by the United States Department of Agriculture, Division of Chemistry).

	Wheat used (cleaned).	Chop from first break.	Chop from second break.	Chop from third break.	Chop from fourth break.	Chop from fifth break.	Chop from sixth break.	Bran 18 per cent. to 24 per cent. of the wheat.	Shorts, fine offal, 1 to 4 per cent. of the wheat.	Germ.	"Bakers" flour.	"Patent" flour (a mixture of the best grades made from the wheat).*

DISCUSSION.

The CHAIRMAN, in opening the discussion, regretted that he had a comparatively slight knowledge of milling machinery, having picked up the little he did possess from the author in conversations he had had with him on the subject. He was interested in the subject from two points of view, the grower's and the consumer's. From the latter's point of view he quite agreed with the conclusions stated by the author, viz., that the amount of nourishment to be derived from the English white loaf of to-day was quite as great as that which was derived from the loaf made fifty years ago. It might be the case that the loaf of to-day had not the flavour it had when manufactured entirely from English wheat as it was fifty years ago; on that he could not pass an opinion, but he had very carefully studied the question of the food value of the present-day loaf, and it seemed to him that the case for white bread had been entirely made out. He had no sympathy with those who stated that the English grower of wheat had a grievance, because the labourer of the present day was supplied with bread which was not so nourishing as that which was consumed by his father. From the grower's point of view, there were some things to which the author had alluded with which he (the speaker) was not so well satisfied. The author had stated that the millstone, which was very suitable in machines for grinding the wheats of England thirty or forty years ago, was quite unsuited for dealing with the wheats the miller desired to grind at the present time; in other words, modern milling machinery was fitted to deal with a class of wheat which the English farmer did not grow. That was a thing which those interested in English agriculture must regret. A great deal of attention had been given within the past few years to the production of English wheats which themselves would possess the qualities of the mixed wheats which the millers now converted into the flour used for baking purposes. This was a subject which was outside the one under discussion, but it might be of interest if he stated that, with the help of the author, the Cambridge University Department of Agriculture was now producing types of English wheat which were fitted for modern English milling machinery, and for the modern bakehouse.

Mr. BRYAN CORCORAN said that milling in the olden times required skill and dexterity, but the knowledge now needed was more scientific and less empirical. The aim of the old miller was to make as much flour as he could at one operation, with as few middlings as possible while cleaning the bran. The whole of the meal passed through a flour-dressing machine, the waste offals going on to a jumper, which was simply a screen, the whole of the products thus being obtained. Now the operation might be said to be quite different. Low grinding with millstones was in operation at the present time, but in the old days high grinding with millstones was in vogue, the difficulty with the latter being that there was less fine flour and more middlings, the middlings being the cause of the trouble. With the low grinding the fine middlings remained in the flour, and some people seemed to think that that added to the flavour. In the high grinding process, all those products, except the first flour that was produced, had to go through successive operations afterwards, and when the flour was produced they were passed back with the other flour. He thought the roll-milling process consisted in cutting up the wheat into small pieces successively by passing it through fluted rollers, so that all but the hard portions were taken away after each rolling and treated again. By that process a certain amount of clean white semolina was produced, which only needed to be reduced to form flour; that flour could be dressed coarsely and was better ground than English. To get back the other products involved a

great many different processes. Undoubtedly the flour produced was very much cleaner and whiter than it used to be, and it satisfied the baker, which seemed to him the only thing that was necessary. As a consumer he would certainly prefer the old-fashioned way, but from a business point of view the more scientific way of getting a purer and whiter article was the desirable thing.

Mr. W. A. VERNON thought the subject of the paper was very little known to the public, and in many ways misunderstood. As the author had very clearly shown, the milling of the present day was far superior to that of years past, the millers having entered into the subject from a scientific point of view. Very few members of the ordinary public appreciated the vast amount of work which had been done for them by the miller in cleaning the wheat and eliminating all extraneous dirt, while by the action of air all the light material was removed, and only the best part of the kernel left for consumption. The finest proteids and the most nutritious part of the grain only, were given in the highest quality of flour, which naturally was the best for human food. He thought the paper would enlighten most people on the subject of the food they ate in the form of bread.

Mr. A. D. HENDERSON thought English people liked to have varieties in diet, and if for no other reason than that he considered that meal breads in various forms were extremely useful, it not being desirable to tie the people of this country down entirely to the use of white bread. The question of stone-made flour had been referred to in the paper, and, in his opinion, stones were very useful for grinding soft wheats, and such wheats as were grown in this country.

Lieut.-Colonel ALLAN CUNNINGHAM desired to contrast the highly scientific process of grinding in use at the present day in all civilised counties with the unscientific process of grinding on a very large scale amongst the huge population of North-West India, which was essentially a wheat-eating population. The wheat was ground there in hand stone mills; the grinding was coarse, and separation of the bran very imperfect, there being a good deal of bran in the so-called flour. The bread was unleavened bread, whereas the bread eaten in this country was leavened bread, which made an immense difference in its effect on the constitution. The native flour was simply kneaded with water, and quickly heated over a griddle. With the addition of a little milk, butter, and salt, that was the staple food of the population. The effect of the diet was that the population were inferior on the whole in physique to Europeans, but it must be remembered that they did not have a varied diet. The people had extremely beautiful teeth which they carefully cleaned. One very curious effect. which was always ascribed to the eating of the native ground wheat, was that the natives were extraordinarily subject to stone, even little children frequently having big stones in the bladder.

Mr. R. SCHINDLER thought the paper gave a great deal of instruction which was very much needed, and wished the points made in the paper could be brought prominently before the attention of the public. The British public was not simply ignorant on the question of the production of flour and bread, but was absolutely misinformed, and labouring under serious misconceptions. A change had taken place in the attitude of the people of this country towards industrial processes. Years ago people did not trouble about how things were produced, but now they wished to know the ins and outs of everything, with the result that newspapers and popular magazines, which were always ready to do what the public wanted, had undertaken to gratify their curiosity. Unfortunately, the journalist who wrote articles on the subject very seldom thought it necessary to obtain any information. About 30 years ago he went into a vegetarian restaurant, and was presented with a short pamphlet setting forth the iniquities of eating white bread; and many of the leading articles which appeared in the present day in the daily papers were simply a repetition of that old pamphlet. Journalists seemed to have no regard for what had happened since that time, not one of them apparently being aware of the experimnts of Professor Schneider, which proved that the facts were in opposition to their theories. The newspapers were perpetually confusing the question of the amount of nutriment in a given material with the amount of nutriment obtained from it, two entirely different things. For instance, sheep fed on grass, and it was hardly possible to find anything less nutritious than such food, and yet from that food, so largely deficient in nutrition and weak in proteids, the sheep managed to make some most nitrogenous mutton abounding in proteids. Another great fallacy which newspapers always indulged in, was that they seemed to think the question of the nutritious character of bread was a matter of very great importance. As a matter of fact it was only of slight importance, because the total quantity of bread consumed was not very large, statistics showing that the consumption of bread in a working man's family amounted to less than one-seventh of his food consumption. One interesting point raised in the paper was the question of growing wheats in England which would produce a hard berry. Experiments were still being carried on, and he hoped the author would soon be in a position to give information on that interesting subject.

Mr. R. A. SIDLEY remarked that when he started flour-milling in Lancashire, nothing but millstones were used, and it was a very rare occurrence to get a sack of English wheat. He therefore thought it could not be contended that roll mills had done the

English farmer so much harm as they contended. The lay press seemed to think that English millers were trying to give the people of this country poison for amusement, and did not give them the credit for making the article which was demanded. In his opinion the farmers had done very little to improve their methods, and he did not believe that, if Mr. Humphries discovered a suitable wheat for them, they would grow it, because they were the most unprogressive part of the community.

Mr. WILLIAM MARK said it had always been the custom in this country to put flour in sacks of 20 stones, but the difficulty at the present day was to find men who could carry such a sack of flour on their backs. He suggested that millers now used what they called bags or half-sacks, because of the impossibility of finding men who could carry a heavy sack of flour He brought the question forward in order to ask, from the standpoint of a food reformer, whether there was any ground for the supposition that it was the ultra purity of the flour on which Englishmen were fed which deprived them of the stamina to enable them to carry 20 stones of flour. While giving every credit to the millers of England for the splendid manner in which they provided the article demanded by the consumer, he did not think it was any detriment to the miller to suggest that perhaps the demand of the consumer was wrong. He suggested it was not a question of what flour the millers should make for English consumers, but what flour the English consumers would be well advised to consume. It was necessary to get a little further back to nature, and to take a lesson from the people of North-West India, to which Colonel Cunningham had referred, where large sections of the population lived almost entirely upon cereals. He maintained that far more was to be feared from the half-starved populations of the world than from the overfed and dyspeptic nations. For instance, the people on the American continent were celebrated for patent foods and patent medicines, but he did not think very much was to be feared from them as a competitive nation. On the other hand, half-starved Germans and the people of Silesia—who fed on wheat, and, if the supply failed, on rye—displayed the qualities which used to be the characteristics of Englishmen, and which he was afraid, from personal observation, were not now obtainable at a salary of 25s. a week.

Mr. FRANCIS DAVIES thought it might be of interest if he stated, in reply to the last speaker's remarks, that some years ago a test was made in California as to the amount of work which men could do in carrying heavy weights and light weight, and it was found that a very much greater amount of work could be done in a given time, with less fatigue, by using small rather than large sacks. He therefore thought the reduction in the size of the sack was not a proof that the men had deteriorated from using white flour. The modern mill was a labour-saving appliance, which in one way was not a benefit to the working population; but it enabled the miller to produce flour at a much cheaper rate, and he could, therefore, sell it at a less price to the buyer who bought the product. In old times people were satisfied with a very poor class of product, the stone mills not doing justice to the wheat, but, at the present time, with the modern roller mill, quite as good results could be obtained from English wheat as were ever obtained in the past. The author had referred to dirt remaining in the inside crease of the wheat. A brush would not take off that dirt, but it must be removed by what was called the first break. A certain amount of flour came away in that break with the dirt which was in the crease; but anyone who desired to escape eating that dirt, could do so by using only the highest class of flour, because the first break flour never found its way into that article.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Humphries for his exceedingly able and instructive paper, said the author stood in the very front rank of his profession, and was looked upon as one of the authorities on the subject of milling and the milling industry. Mr. Humphries had taken a leading part in connection with the work which had been carried on for the last ten years for the improvement of wheat. The work had been carried out in part by an Association, of which Mr. Humphries was chairman, and in part by the Agricultural Department of the University of Cambridge and the Experimental Station at Rothamsted. The scientific workers regarded Mr. Humphries as their much trusted technical adviser, and he was one whose advice had been of the greatest possible value and assistance.

The resolution was then put and carried unanimously.

Mr. HUMPHRIES, after thanking the audience for the exceedingly kind manner in which his paper had been received, stated that Mr. Mark inquired whether it was a fact that the demand for half-sacks was due to the weakness of the carmen. That was not the case, the demand being made seven to eight years ago from the bakers, who sent in something in the nature of an ultimatum to the millers, that if the flour were not put into half-sacks they would not deal with them. It was a very curious coincidence that the millers had an appeal made to them by the carmen of London, 105 of whom signed a round robin saying that they desired the full sack to be continued, only two being in favour of the half-sack. The carmen preferred carrying the full sack to the half-sack because it saved them so much time in delivery. Colonel Cunningham had referred to a new and

interesting point. He (Mr. Humphries) had been suggesting that if a man lived wholly on white bread he would get sufficent ash from it fully to satisfy the demands of nature in that direction. The Indian people evidently took more ash than English people did, and suffered badly from stone as a consequence. If that was caused from an overdose of food which contained an excess of ash, personally he would rather eat wheat flour such as was produced in this country. The main point to which he desired to call attention was, that it was supposed that modern milling was detrimental to the farmer because it could not deal with soft wheats. That was an absolute fallacy, for which there was not the slightest ground of suspicion. The roll mill could tackle anything that a stone mill could tackle, It might easily happen that the wheat was too soft altogether for the millstone, but the roll mill, although it would not do such good work upon that soft stuff as it would do upon wheat properly mellowed and in good condition, would do better work than the millstone could do. Another speaker had said that modern processes spoiled the flavour. He did not agree with that suggestion for one moment, for the reason that he had several times taken flours and milled them, first by one process and then by another, and at the finish he could not tell the difference in flavour between them. It was an undoubted fact, however, that the whiter bread was invariably better flavoured than the dark bread, the latter having a distinctly bitter taste, the characteristic of the addition of bran. The hard wheats which broke up into fine particles, extreme darkness being obtained owing to the presence of husk, undoubtedly gave a worse and not a better flavour. Referring to a remark made by the Chairman, Fife wheat had been grown in England for five years in succession, and had not lost its hardness, and wheat had been grown in England for fourteen years which had not lost its hardness. As a matter of fact, hardness and high nutriment did not go hand in hand. Some of the hard wheats of India had a low nitrogenous content; but, speaking in a general way, the Fife wheats grown in England were actually not only a more saleable article, but a better article from the dietetic point of view. He had had analyses made of wheats grown side by side, and the Fife wheats showed they contained 2½ per cent. more glutin than the soft wheats. Manuring did not enter into the question at all; it was simply and solely the fact that the harder wheats did manage by some method to extract from Nature more nitrogen than the other wheats grown alongside, although the soil and the treatment by the farmer were exactly the same. English millers, so far from wishing in any way to depreciate the value of English wheat had, for the last five years, spent a great amount of time and trouble, fortunately with every prospect of success, in raising in England wheat that should be equal to the best American wheats and, in addition, from the dietetic point of view, actually more nourishing because they contained a far higher percentage of nitrogenous products.

ARTS AND CRAFTS.

Furniture.—In the recent movement in industrial art which has covered pretty well the whole field of artistic manufacture in this country, furniture has not by any means lagged behind. Indeed, nowadays fashions change almost as rapidly in furniture as they do in frocks. In place of the old-fashioned mahogany suite we have all sorts and kinds of novelties. In fact it is easy enough for anyone who knows anything about it to say, in looking at a modern room, about how long ago it was furnished, or rather when the furniture was bought. We have had, of course, work of the most up-to-date kind, good, bad, and indifferent thrust upon us for some time past, and there have been in connection with this kind of furniture some interesting developments, both of the form of the objects and of the method of decorating them. But all the time, side by side with the modern movement, there has been a distinctly antiquarian one. We have suffered from what amounts almost to a mania for Chippendale, Sheraton, and other furniture of the eighteenth and nineteenth centuries. Better by far a Chippendale chair, no matter how ricketty and shaky and useless, than any modern production, be it never so useful or so well proportioned. What did it matter if the legs were stuck fast with glue, so long as the piece of furniture was a real antique. That was all very well some time back, when real pieces of old work were to be picked up at a reasonable price and in good condition. But of recent years that has been quite impossible, and the ordinary householder with a taste for Sheraton, or Hepplewhite, let alone Chippendale, has been obliged to content himself with modern imitations. And thus, side by side with the wildest of modern individualistic furniture, we have had quantities not merely of adaptations, but of direct copies of the work of the celebrated makers of the Georgian period. Further, the taste for this kind of thing has been fostered (or has it, perhaps, been a cause?) by the present desire for what is called in some quarters "early English design"—a term commercially applied to work not earlier than the Jacobean, and sometimes as late as the Victorian, period. For some two years now, wallpapers, cretonnes, and hangings of various sorts in the style of Jacobean crewel work, or in the more naturalistic manner of the days of our great grandmothers have been in great demand—and designs which some time ago would have been dubbed old-fashioned and hideous are now declared to be quaint and delightful. People with common sense or taste naturally realised that if somewhat obtrusively modern hangings, covers, and wallpapers would not go well with Chippendale and Sheraton chairs and tables, neither did furniture of an up-to-date type fit happily into rooms papered with wreaths of roses and bunches of flowers, or upholstered in the "last thing" in Victorian chintzes. Modern Chippendale and inlaid Sheraton furniture have been with us for some time now, and in the natural course of events

they are being followed by work of a somewhat later period.

Satinwood Furniture.—Satinwood was first imported from the East Indies somewhere about the end of the eighteenth century. The beautiful marking of the wood quickly brought it into popularity for small tables, chairs, and other articles of furniture, and the taste of the day settled its treatment. Table tops and other flat surfaces were occasionally left bare, to show the beauty of the wood; sometimes they were enriched with tulip wood—or some other kind of inlay. But it was a time when the painter was in high favour. Cipriani, Angelica Kauffmann and others were busily working in England—and a certain amount of quite elaborately painted furniture was being made by Sheraton, Heppelwhite, and others. Thus it was by painting that this new satinwood furniture was mainly decorated—and the painting was in the style in vogue at the moment. Painted medallions were largely employed, and these were filled with cupids, scenes from classical fables, and other subjects in fashion; whilst swags, wreaths, garlands, masks, musical instruments, and such like motives provide the ornamental portion of the decoration. The modern productions in satinwood, which are filling the shop windows from Bond-street to Tottenham-court-road, are strictly on the lines of the old. Indeed, they are largely copies of old examples both in shape and decoration. In a few cases, the wood is so arranged that the waving lines of its markings form a pattern—occasionally a little inlay is judiciously used in borders and such like, but the largest part of the work is painted, and rather heavily painted, too. It seems a pity that, in the case of a wood so beautiful both in marking and in colour as satinwood, the wood is not more often left (as it was in the best old work) free from paint. The decoration may recall the old work, it may be in keeping with the style of the furniture, but it does not add to the beauty of the texture or the surface of the material. Painting on wood, moreover, however satisfactory it may be for the time, cannot in the nature of things have the same lasting qualities as inlay. It always seems rather odd that more has not been done in the way of slightly grounding out the design, so that the painted parts would not be on the same level as the wood surface. This would have the double advantage of making the paint less likely to wear off, since it would be in a less exposed position, and of rendering its renewal easier when it had worn off.

Silversmiths' Work.—Silversmiths' work is perhaps the craft above all others in which the modern English artist-craftsman can be said to have really found himself and evolved a style which, without being extravagant or *outré*, is really distinctive and original—a style, too, which has a simple dignity of its own. This may be due in part to the fact that some of our most successful artistic silversmiths are workmen, who have arrived at art by way of mastery of their trade, and not artists who have taken to craftsmanship. It is at this season of the year that we really have he best chance of seeing what is being done by the different workers. Many of the galleries contain cases of work by well known craftsmen, and some of the makers have special shows at their own studios. Of course, the season, and the demand for Christmas presents at a fairly moderate price, affects the character of these various exhibits. A good number of the objects shown are small and unimportant — but the forks, spoons, serviette rings, salt cellars, mustard pots, and the like are often far better in design than anything it would have been possible to buy in days not long gone by, and the prices sometimes compare not unfavourably with those charged for ordinary trade work. And, these small things designed to appeal rather to the casual purchaser, though numerically more important, are not the mainstay of the shows. Artists so deservedly well known as Messrs. Car and Ramsden, Mr. Spencer, and Mr. Nelson Dawson, to mention only a few names, are naturally not content to be represented entirely by work of a comparatively trivial kind; and it is satisfactory to notice that work is being done for ecclesiastical purposes, as vigorous as it is dignified, which, though markedly original and individual, keeps its own place, and would not be conspicuously and hopelessly out of place in fairly ordinary surroundings. The cross and candlesticks for the Bishop of Rochester, the Rochester Diocesan crozier, the mace for the Bishop of Southwark, the pastoral staff for the Bishop of London, and a really beautiful sanctuary lamp—all of which have been on view during the last few weeks, are works which make one feel that here is a craft which is very much alive indeed, and is being carried on by earnest and competent workmen, who, while working on their own lines, are not afraid of looking at what has been done before by the masters of long ago. Here are men possessed of an individuality which is strong enough to take care of itself and has, therefore, no need to be afraid of being lost when it comes in contact with other minds. On the whole the least satisfactory part of the more serious silversmiths' work is the enamel, which often looks too trivial and tinselly for its setting. One cannot help wondering whether on rather massive work, opaque *champlevé* enamel would not be more in keeping than translucent *cloisonné*. But, as a certain amount of *champlevé* enamel is now being made, we may hope at no very distant date to have a chance of seeing how it looks on the silversmiths' work of the twentieth century. Finally, it is hopeful to see that, when a craft is carried on by working artists, who consider their craft as seriously as they do their art—and who have thought it worth while to study it as seriously—they not only find a market for their work, but do something towards levelling up the standard of ordinary trade production—and so have a real effect upon the output of the country as a whole.

CORRESPONDENCE.

OBJECTIONS TO THE COMPULSORY INTRODUCTION OF THE METRIC SYSTEM.

I observe by your issue of the 14th inst. that you have opened your columns to correspondents who desire to add to the recent discussion on this subject. May I, therefore, hope that you will find space for the accompanying letter from a firm of silk merchants who deal with the statement made by Col. Sir C. M. Watson as to the continued use of the "aune" and "denier" in that industry. It appears to me to be as reasonable to claim that the metric system is unsuitable for general use because in France some old names are still used for new measures, as it would be to say that English is not a suitable language for our commerce, because the Welsh language is still spoken in some of the mountain districts in Wales.

The mention of Herbert Spencer's name commands universal respect and consideration, but Mr. R. Kaye Gray, who quotes from Spencer, cannot agree with him (whose chief objection to the adoption of the metric weights and measures was based on a preference for a duodecimal system), and at the same time advocate a decimal system based on the inch as the unit. If anyone still believes that a duodecimal system is possible, let him construct a multiplication table, and he will not have proceeded far before he realises the impossibility of such a project.

Perhaps you will allow me to reproduce one table, using therein the signs, "T" and "E," to represent 10 and 11.

4 × 1 = 4
4 × 2 = 8
4 × 3 = 10
4 × 4 = 14
4 × 5 = 18
4 × 6 = 20
4 × 7 = 24
4 × 8 = 28
4 × 9 = 30
4 × T = 34
4 × E = 38
4 × 10 = 40 (*i.e.*, our present 48.)

One speaker at the recent meeting read a letter from Messrs. Willans and Robinson stating their reasons for opposing the adoption of the metric weights and measures. I am not able to trace any argument against the metric weights and measures being used for commercial purposes, in the announcement of this firm.

The use of the metric system in the workshops in question was entirely a voluntary matter, and the fact that Messrs. Willans and Robinson had to use two systems of course added to their expenses. If their English as well as Continental customers had used the metric system while they (Messrs. Willans and Robinson) did, I doubt whether there would have been any recantation by this firm.

But no one proposes to make it obligatory on any manufacturer to construct engines, machines, or cotton goods to the metric scale, that is altogether a different thing from buying and selling by that system.

Messrs. Willans and Robinson said that their workmen had no difficulty in using the metric measures, and they still use the metric system, they say, for their continental trade. Quite so, this supports our case.

It is strange that this important firm should be supporting an Association which admits the need for a reform of our weights and measures, and advocates a new British system based on the inch as a unit, the inference being that Messrs. Willans and Robinson are prepared to try that scheme in their works.

To remove some misunderstanding, I should like to say that the firm named were not members of the Decimal Association, and to add that there are firms still which use the metric system entirely in their works in this country.

E. JOHNSON,
Secretary, Decimal Association.

Oxford-court, Cannon-street, London. E.C.
December 18th, 1906.

The Secretary,
Decimal Association,
London, E.C.

32, Snow-hill, E.C.,
December 13th, 106.

DEAR SIR,

In reading the paper by Col. Sir C. M. Watson, before the Society of Arts, on some objections to the metric system, we notice that one of the points he made against the metric system was, that in France the metric standard had not completely replaced the old measures, giving as a practical instance the silk industry, in which "the skeins are still based for length on the 'aune' and for weight on the 'denier.'"

As silk merchants having to deal daily with these matters, and having a practical experience of them both in France and Italy, we wish to state that Sir C. M. Watson is under an entire misapprehension. Silk yarn, it is true, is sized by the denier, but the denier itself, as officially recognised all over the globe, is based on the metric system. The denier represents a weight of 0·05 grammes per 450 metres of silk Thus, if a silk yarn is stated to be 20 deniers, this means that 450 metres of the silk weigh 0·05 × 20 = 1 gramme. Although in a few of the private reeling establishments in Lyons it is still customary to give the size in the old denier, which was in force before the introduction of the present system; in such cases the official denier is always stated as well on the reeling notes under the title "titre legal," and anyone giving the size in deniers is always understood to mean the official measure.

As regards the length of the skeins, this may be originally based on the "aune," but when referred to it is invariably the custom to give the measure in centimetres. Further, when the length of yarn to the skein is a fixed quantity, it is invariably a definite number of thousand metres—usually 10,000.

Under these circumstances it is difficult to see where Sir C. M. Watson's contention comes in, so far as the silk trade is concerned.

Yours faithfully,
(Signed) RHEINBERG & Co.

GENERAL NOTES.

CANALS AND WATERWAYS.—A statement appeared in the *Journal* of 7th December, to the effect that the Royal Commission on Canals and Waterways had completed its investigations so far as England is concerned. This is incorrect, and indeed is inconsistent with the statement contained in the Report itself that later on it is proposed to hear further witnesses from England, Wales, and Scotland. Since the date of the Report, the Commission, it is understood, have held sittings in Ireland as well as in London. They have now adjourned till February next, when it is believed that they will have further evidence about Ireland, Scotland, and Wales, and a large amount of evidence about canals and waterways. It is also believed that the Commission would welcome further evidence from representatives of important industries who are interested in water transport on account of its cheapness, and if, therefore, there are any Members of the Society connected with the coal and iron trades, or with other manufactures and industries relying upon cheap transport, who have not yet given evidence before the Commission, and are in a position to do so, it would be as well for them to take steps to bring their views before the Commission, the address of which is 54, Victoria-street, S.W.

NOBEL PEACE PRIZE.—The Board of Education have received through the Foreign Office an intimation that, in order to be eligible for the Nobel Peace Prize, which will be awarded in December, 1907, candidates must be proposed to the Nobel Committee of the Norwegian Parliament before February 1st next. The following persons alone are qualified to recommend candidates:—1. Past and present members of the Nobel Committee of the Norwegian Parliament, as well as members of the Advisory Board of the Nobel Institute. 2. Members of the Legislatures and Governments of different countries, as well as members of the Conseil Interparlementaire. 3. Members of the International Arbitration Court at the Hague. 4. Members of the Commission of the International Peace Bureau. 5. Members of the Institute of International Law. 6. University Professors of law and political science, of history and philosophy. 7. Persons who have received the Nobel Peace Prize. The Nobel Peace Prize can be granted to an institution or an association, not only to an individual Inquiries for further information should be addressed to the Comité Nobel du Parlement norvégien, Drammensvei 19, Kristriania, Norway.

SIAM.—In reporting upon affairs in Siam (Cd. 2682) Mr. Acting Consul Lyle refers to an interesting feature in the distribution of cotton goods, namely the rise of a class of Indian packmen. These individuals are spreading on all sides of the river and railway highways hawking goods, and the Chinese trader of the Delta and the Provinces is beginning to find his position seriously menaced. Through these men the British Indian cotton trade is yearly obtaining a greater control of the retail cotton market. In steel bars, plates, girders, &c., the local demand is increasing, more particularly for girders, which are rapidly taking the place of teak for building purposes, owing to the very high price and increasing demand for teak on the home market. Steel is also gradually but slowly replacing teak for lighters, cargo boats, and small steamers. During 1905, milling machinery for eleven rice mills, averaging £5,000 per mill, was imported or ordered. Of this £35,000 was British and about £18,000 German. There has been a noticeable increase in the value of the imports of cycles and motors—from £1,023 in 1904 to £22,127 in 1905. The cars which have found their way to Bangkok, though of Continental makes, have been for the most part secured through British agencies. It is surprising that German shipping does the larger part of the carrying trade with Siam. Last year the proportion carried in German bottoms was 64 per cent., Norway coming next with 17 per cent., the British per centage being only 11 per cent.

CHEFOO AND KIAOCHOU.—The trade of Chefoo would seem to be seriously threatened by Kiaochou. In his report on the trade of the former port for the years 1903-5, Mr. Consul O'Brien Butler says that the Germans are sparing neither money nor trade in preparing Kiaochou to become a rival to Chefoo. The harbour at Chefoo is at present in a lamentable condition, being exposed to the strong northerly winds which prevail during the winter, and having no facilities for loading and unloading cargo. It is very difficult to tranship cargo in severe weather, and the delays which are thus caused prove very serious to shipping. At Kiaochou, on the other hand, a magnificent harbour has been built, with wharves and warehouses, and with the additional advantage that goods can be landed from the ship direct into railway trucks. Kiaochou is also in communication with Chuan Fu, the provincial capital, and thus possesses a great natural advantage over Chefoo, both with regard to import and export trade. It is, therefore, of great importance that Chefoo should be provided with some effective harbour improvement without delay if she is to maintain her position.

Journal of the Society of Arts.

No. 2,823. VOL. LV.

FRIDAY, DECEMBER 28, 1906.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 2, 5 p.m. (Juvenile Lectures), BENNETT H. BROUGH, "Perils and Adventures Underground."

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 2nd and 9th, at 5 o'clock, by BENNETT H. BROUGH, F.G.S., F.I.C., F.C.S., on "Perils and Adventures Underground."

Each Member is entitled to a ticket admitting two children and an adult. A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received. Members who desire tickets for the course are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

ARTIFICIAL FERTILISERS: THEIR NATURE AND FUNCTION.

BY A. D. HALL, M.A.,
Director of the Rothamsted Experimental Station, Lawes Agricultural Trust.

Lecture I.—Delivered November 19, 1906.

THE NUTRITION OF THE PLANT.

In talking of an artificial manure, one has a perfectly clear idea of the meaning of the term ; to find, however, a satisfactory definition is by no means easy. To the farmer certainly it means something which he receives in bags and applies to the land in hundredweights rather than tons per acre. With these two ideas in our mind—that we are dealing with an article of commerce, and with a concentrated one—we may dispense with any more formal definition of what constitutes an artificial fertiliser.

Nor, with the limited time at our disposal, need we spend much time over the early history of artificial manures. Men of an experimental turn of mind must have been putting all sorts of things on their land from the beginning of time. The virtues of gypsum and bones were certainly known to the Romans ; and, to come down to more modern times, we find a man like William Ellis, writing in 1736, was well acquainted with the use of such bodies as woollen rags, bones, soot, malt dust, and oil cake residues as manures. The real history of artificial fertilisers begins with the nineteenth century, because not until then was the knowledge of chemistry sufficiently advanced to provide any basis for a theory of the nutrition of the plant. Without such a theory all observation of the good effect of this or that substance on the crop was merely empiric and possessed no value beyond the occasion.

To trace the building up of our accepted conception of the course of a plant's nutrition would have an interesting story, in which Priestley, de Saussure, and Liebig are the outstanding names, though many others played their parts, either creative or controversial ; but it would require a lecture for itself. In the main, though there are bye-paths still to be explored, the great issues may be considered as settled ; indeed they are just beginning to receive the final sanction of age and orthodoxy in the shape of the assaults of the crank, who starting *de novo*, rediscovers all the errors and fallacies which the old masters had patiently and laboriously cleared away.

If we take any living plant and reduce it to its elements we find but a small range of substances; water forms the greatest portion of the plant, the rest is almost wholly composed of

compounds of carbon with hydrogen and oxygen, approximately in the proportions which make up water. Of the dry matter of the plant at least half is carbon; oxygen and hydrogen constitute most of the remainder; then a certain restricted number of other elements are present in much smaller quantities. Nitrogen constitutes 2 per cent. of the dry matter; the others, which are found in the ash when the plant is burnt, make up a further 2 per cent. These ash constituents comprise sulphur, phosphorus, silicon, and chlorine among the non-metals; potassium, sodium, calcium, magnesium, and a little iron and manganese among the metals. Traces of other metals occur from time to time in the ashes of plants growing on soils which happen to contain them, but they are unessential and may in this connection be neglected.

H. T. Brown, the leaf, which may still be attached to the plant, is enclosed in a flat air-tight box with glass sides, through which sweeps a rapid but measured current of air. The issuing air which has passed over the leaf is led into an apparatus for the determination of the carbonic acid (and if need be of the water) it contains; at the same time a parallel experiment without the leaf measures the proportion of carbonic acid and water in the incoming air. Thus the amount of carbonic acid absorbed, and therefore decomposed, in a given time by a leaf, whose area can be afterwards measured, is directly determined, and such factors as illumination, temperature, can be varied at will. The energetics of the process have been worked out by Dr. Brown and Mr. Escombe, from whose paper the following examples have been selected :—

TABLE I.

Plant.	CO_2 absorbed per sq. dm. of leaf per hour, c.c.	Water transpired. Grams.	Energy in calories per sq. cm. of leaf per minute.				
			Solar radiation falling on leaf.	Solar radiation absorbed by leaf.	Energy required for assimilation.	Energy required for transpiration.	Energy lost by radiation and convection.
Polygonum, June 19....	3·758	1·054	0·1942	0·1256	0·0031	0·1041	0·0184

Helianthus, August 4 ..	2·134	1·259	0·2569	0·1762	0·0017	0·1243	0·0502

Carbon then is the main element in the plant's economy, and we know that it is obtained by the plant from the carbonic acid in the atmosphere, through the agency of the living cells in the leaf which contain green chlorophyll. The carbonic acid is taken in through the small openings in the skin of the leaf, the stomata; it is decomposed by the chlorophyll-containing cells and the carbon is retained in combination with the elements of water, so that it is first identifiable as sugar and then as starch, at the same time oxygen is returned to the atmosphere. This decomposition is one which necessitates an external supply of energy, which is found to be derived from the light incident upon the leaf, the process stopping in darkness, and for low illuminations becoming proportional to the amount of light falling upon the leaf.

The conditions affecting this process of photo-synthesis, the fundamental reaction of the whole plant world, have been subjected to considerable examination of late. In the method which has been adopted by Dr.

These experiments show that the leaf of a plant is not to be regarded as a very efficient machine for the decomposition of carbonic acid, since in no case was more than 1·66 per cent. of the total incident energy on the leaf used for photo-synthesis, so that even dull, diffuse daylight can amply provide a growing plant with the energy it wants for assimilation. The process, however, is limited by many factors, any one of which may fix a minimum rate at which assimilation will take place, however favourable the other conditions are. Temperature, the supply of water, the proportion of carbonic acid in the air, the number and area of the stomatic openings, are all limiting factors of this kind, as also is the supply of other nutriment to the plant. To take an example which bears more particularly on the subject of these lectures: if we compare two of the Rothamsted mangel plots (see Table II.), which receive the same supply of nitrogen and phosphoric acid, we find that they produce approximately the same weight of leaf, indeed the similarity would be

still closer if the comparison were made when the leaves were in full activity, and not at the end of the growing season. One plot, however, receives a dressing of potash salts, but not the other, and the plot with potash produces nearly 2½ times the weight of roots grown upon the other plot without potash. Now this difference in weight is almost wholly due to sugar and other carbo-hydrates, which were manufactured in the leaf and then passed on to the root for storage, yet the two plots possessed practically the same leaf development working under identical conditions of illumination, carbon dioxide, and water supply. But in one case the photo-synthetical process had been limited by the want of potash; all the machinery was there and the power was in excess, but the machinery was running idle for the lack of one necessary link—in this case the potash. (See Table II.)

4A	Nitrate of soda, superphosphate & potash	3·25	28·95	2·223

Though the compounds of carbon with hydrogen and oxygen make up so much of the solid matter of the plant, the remaining substances, comparatively small in amount as they are, are still all important to the process of growth. The part they respectively play and their mode of entry can best be illustrated by the method of water cultures, of which Fig. 1 shows an example. By this

FIG. 1.

method the roots of young seedling plants are just allowed to dip into a large jar of water in which salts of the elements found in the plant are dissolved. A complete solution might be made up as follows :—

	Grammes per litre.
Calcium nitrate	0·7
Potassium phosphate	0·6
Potassium chloride	0·8
Magnesium sulphate	0·3

with a trace of ferric chloride.

This will contain all the elements, except silicon, normally found in plant ashes, and under such conditions the plant will grow and go through its whole cycle of life, assimilating freely, producing large quantities of dry matter, setting flowers, and ripening healthy seed. Certain precautions have to be taken, but if the right conditions are assured, the growth of a plant in a water culture is perfectly normal, and may be taken, as far as the plant is concerned, as representing the course of its nutrition in the field. The advantage of the method lies in the fact that it is possible to vary the composition of the nutrient solution by omitting in turn from successive jars each of the salts used in making up the complete solution, thus obtaining media for the plant containing no nitrogen, no phosphorus, no potassium, &c., the other constituents found in the plant being present in each case. The result of one such series of experiments is shown in Fig. 1, which illustrates that when, *e.g.*, nitrates are omitted from the culture solution the plant is quite unable to grow after it has used up the material in the seed, however freely it may have been provided with potassium, magnesium, &c. The nett result of such experiments, in agreement with the one shown in the photograph, is that a plant must obtain by means of its root its nitrogen and its ash constituents from simple inorganic compounds dissolved in the water.

Of the elements found in the plant, nitrogen in combination, phosphorus, sulphur, potassium, magnesium, calcium and a little iron are indispensable to the growth of the plant and cannot be omitted from the culture solutions. Sodium, silicon, and probably chlorine, though invariable constituents of the ash, are not necessary and can be dispensed with. From these water-culture experiments we arrive, then, at the conclusion that the plant must draw certain elements, in quantities which are small indeed compared with the weight of the crop but nevertheless indispensable, out of the soil by means of its roots, the rest of the plant being built up from air and water. The further deduction would appear to be simple, that the manure a plant wants will consist simply in these bodies, other than carbon, hydrogen, and oxygen, which are mainly left behind when a plant is burnt. Indeed, it was on these lines that Liebig, who first of all devised a theory of manuring, proceeded to construct an artificial fertiliser. Put into the soil, he said, exactly what a good crop of the kind normally removes, and you have satisfied all the manurial conditions necessary for a maximum crop; and on this basis manures were compounded for the various crops, which, however, failed to satisfy the farmer who used them. Not only did Liebig's own manures prove a failure, but his theory of manuring was rudely traversed by the field experiments which Lawes and Gilbert had just begun in this country. His theory, indeed, true enough for a water culture, breaks down in the field because it takes no account of the soil; and the soil is not merely an inert medium to anchor the plant and convey the manure to it when convenient, but contains itself an enormous potential reserve of plant food.

We may take, by way of an example, the Rothamsted soil. On the one hand, it is neither richer nor poorer than the majority of British soils and it has no abnormal characteristic, but may be taken as a very fair average type; on the other hand, there is no other soil about which so much knowledge has been accumulated.

The accompanying analysis shows, as usual, that the greater part of the soil consists of insoluble siliceous matter of which no account need be taken; there is further a certain amount of organic material, important as containing a store of nitrogen which may eventually reach the plant. In addition, we have various acids and salts going into solution in the acids used for the analytical process, and these include precisely the substances that have already been indicated as constituents of the ash of plants; amongst metals, calcium, magnesium, potassium, sodium, with iron and aluminium in quite disproportionate amounts, sulphuric and phosphoric acids, chlorine and silica to supply the non-metals. Read as percentages, some of these amounts seem small enough, but they represent enormous quantities of material in the soil, as will be realised when they are correlated with the fact that the layer of soil at Rothamsted, nine inches deep,

which is taken for analysis, weighs over the area of one acre rather more than two and a half million pounds. Translating, then, the percentages into pounds per acre, 0·1 per cent. of nitrogen becomes 2,500 lb., 0·11 of phosphoric acid becomes 2,750 lb., and the potash rises to 6,750 lb.; also these quantities are in the surface soil only without considering the lower layers into which the plant roots penetrate

freely. A comparison of the materials in the soil with those taken away by ordinary crops at once leads to results which seem paradoxical, so much greater is the stock of plant food in the soil than any requirements of the crop that further additions of the same stuff in the shape of fertilisers would seem to be needless. The accompanying Table (IV.) shows the amounts of various materials per acre which are on the average drawn from the soil by various crops at Rothamsted.[4]

Roughly speaking an average soil contains enough plant food for a hundred full crops, yet without fresh additions of plant food as manures the production will shrink in a very few years to one-third or one-fourth of the average full crop. Once, however, the yield has reached this lower level it will remain comparatively stationary, affected only by the fluctuations due to season, for an indefinite period. At Rothamsted, for example, wheat has now been grown year after year on the same land for sixty-three seasons, and one plot has received no manure throughout the whole period. In the first few years the crop declined steadily, but since then little or no further drop can be seen. The yield remains at about 12½ bushels per acre for each successive ten years' average, and has considerably overtopped that amount during the last two favourable seasons. This yield, however, of 12½ bushels of corn per acre is only about a third of that obtained on the adjacent plots receiving manure every year during the same period.

These facts lead to a new point of view. I is not merely the amount of this or that plant food present in the soil which must be taken

TABLE IV.—Soil Constituents contained in Average Crops.

into account, but also their mode of combination. The material may be present in the soil and soluble in the acid used for analysis, but yet may be beyond the reach of the plant in a locked up or dormant condition. The plant can only obtain substances which have been previously dissolved in the water contained by soils in the field, hence plant food in the soil is only available for the plant in so far as it can pass into solution. It has been maintained that the roots of the plant itself, in virtue of the acid cell-sap they contain, are capable of exerting a strong solvent action on such insoluble materials of plant nutrition as calcium phosphate, but investigations of this question from various points of view lead to the conclusion that no such external action of the root sap is possible, but that the carbon dioxide excreted by the roots does assist the solvent action of the soil water. The apparent paradox of a soil being poor or impoverished while

yet containing enough plant food to furnish a hundred crops or more is thus explained by the comparative insolubility of these reserves, which can only become available to the plant by passing into solution. To use an illustration, the plant food in the soil may be represented by the capital a man may have locked up in a particular business, the available plant food will correspond to the cash in hand, which may often run dangerously short, however great the capital involved. Similarly a good many of the operations of cultivation have for their end the bringing of the capital of the soil into a circulating form as rapidly as possible and the realisation of a profit from it.

Accepting then the fact that the soil contains a vast store of all the elements necessary to its nutrition but in forms more or less available, it remains to ascertain which of the substances are normally likely to fall below the current requirements of the crop. This is a question that can only be solved by field experiments, and though the solution will vary with each crop and each soil, yet certain general principles at once become evident, and upon them the whole idea of a fertiliser is based. For example, field experiments at once show that certain elements indispensable to the plant, as seen from water-culture experiments, need not be supplied to the crop in the field, since the soil is practically always able to provide a sufficiency. Calcium, magnesium, iron, sulphur, chlorine, and silicon fall into this class; to judge by field experiments alone there are only three elements necessary to the nutrition of the crop, nitrogen, phosphorus, and potassium, which means that soils can usually supply enough of the elements necessary to the plant excepting only of these three. Fertilisers, then, are designed to supply deficiencies in the soil and for all practical purposes are to be regarded as containing compounds of nitrogen, phosphoric acid, and potash, either singly or together. They may also contain magnesia, lime, or sulphuric acid, but these, though equally necessary to the plant, are not counted, since the unaided soil may be trusted to furnish the crop with them.

To illustrate the part played by the soil, a comparison may be drawn between the water-cultures of barley previously illustrated and the results of the Rothamsted experiments upon the same crop grown continuously for over fifty years on the same land. The same series of nutrient substances were employed in both cases, and in the field trials, as in the water-cultures, the part played by any element can best be seen from the result produced by omitting it from a complete manure.

TABLE V.—Experiments upon Barley, Hoos Field, Rothamsted.

Plot.	Character of manuring.	Yield—Bushels of Grain.	
		Whole period 51 years.	Last 10 years only.
1-O	Unmanured	15·3	10·1
4-O	Without nitrogen	20·4	12·4
3-A	Without phosphoric acid	29·4	20·8
2-A	Without potash	39·9	26·8
4-A	Complete manure	42·1	35·1

From this it will be seen that the soil alone is capable of producing a crop which, if small, yet amounts to over a third of that obtained with a complete manure. The omission of potash results in a small diminution of crop, the omission of phosphoric acid in a much larger one, while in the absence of nitrogen the yield falls to less than half, almost to that of the unmanured plot. Of course, in a water-culture the omission of any one of these elements would have reduced the growth to a minimum; in the field the soil has been able to meet the requirements of the plant fairly well as regards potash, less so for phosphoric acid, and very indifferently as regards nitrogen. That the soil is drawing in capital to supply the crop may be seen by comparing the results from the omission of potash over the whole period, and for the last ten years; over the whole period the decline in the yield produced by the omission of potash is only 5·2 per cent, but during the last decade this decline has risen to 23·6 per cent., an indication that the supply of potash originally available for the crop has been largely exhausted.

This experiment also illustrates another difficulty that is experienced in framing a theory of fertilisers; the analysis of a plant, though it would enable one to make up a solution suitable for its growth in water-culture, is no guide to the amounts of the various fertilisers to be supplied to the same plant when growing as a field crop. For example, analysis shows that an average barley crop removes from the soil about 49 lbs. of nitrogen, 21 lbs. of phosphoric acid, and 36 lbs. of potash per acre; yet the addition of 43 lbs. of nitrogen raises the crop from 20·4 to 42·1 bushels per acre, or by 51·5 per cent. of the crop on the standard completely-manured crop; the addi-

tion of 63lbs. of phosphoric acid produces an increase of 12·7 bushels; while the addition of 100 lbs. of potash, the element most abundant in the ash, only causes an increased yield of 5·2 per cent.

To take another example. An average crop of swedes will remove from the soil 98 lbs. of nitrogen, 22 lbs. of phosphoric acid, and 80 lbs. of potash; but, so far from the swede crop requiring a fertiliser which is mainly nitrogenons and potassic, all field experiments and long farming experience go to show that swedes require little beyond phosphoric acid as a manure, with a small amount of nitrogen and potash only in rare cases.

No theory of fertilisers then can be based on the composition of the plant alone. The amount of plant food must also be taken into account, and not only its amount but its availability, which will vary to a considerable extent with the different crops. Growing plants of different species show widely differing powers of obtaining for themselves from the reserves in the soil the quantity of this or that plant food which they require; those differences depending on such factors as the depth or extent of the root range, the duration of growth and the period of the year at which it takes place, &c. For example, compare the effect of withholding potash in the fertiliser from three of the crops under experiment at Rothamsted — wheat, barley, and mangels.

TABLE VI.—Effect of Potash on various crops grown continuously.

	Manures. Nitrogen and phosphoric acid.	Manures. Nitrogen phosphoric acid and potash.	Per cent. increase due to potash.	Potash, pound per acre removed by crop (average).
	Yield. (bushels)	Yield. (bushels)		
Wheat ...... (51 years)	24·0	31·5	31·2	28·8
Barley ...... (51 years)	39·9	42·1	5·2	35·7
	(tons.)	(tons.)		
Mangels ..... (27 years)	7·66	14·03	83·2	300·7

As all three crops are grown on soils which are practically identical, this Table shows that barley is much better able to use the reserves of potash in the soil than are either wheat or mangels, the latter crop being particularly dependent upon a large supply of potash in the fertiliser.

The fertiliser that a crop particularly requires is the substance that it finds some special difficulty in obtaining from the reserves in the soil; and this difficulty may be indicated by a comparative deficiency of the substance in question in the plant's analysis, just as the swede crop, which is particularly in need of phosphoric acid, only removes of it 22 lbs. per acre, as against 98 lbs. of nitrogen and 80 lbs. of potash.

But while it is true that for each of our farm crops we can indicate what Ville has called a "dominant" fertiliser, nitrogen for wheat, phosphoric acid for swedes, potash and nitrogen for mangels, meaning thereby that if the crop is well supplied with its "dominant" by means of fertilisers, it can generally pick up the remaining elements of nutrition from the soil reserves, yet this "dominant" is hardly to be discovered from a consideration of the analysis of the plant. Field experiments form the only guide to the manurial requirements of any plant, field experiments carried on for a sufficient length of time to eliminate accidental variations in the results due to soil and season. Such field experiments have been carried out for wheat, barley, oats, grass, potatoes, mangels and turnips; but for many other crops of considerable importance, particularly in market gardening, this fundamental knowledge of the plant requirements has not yet been ascertained.

A complete theory of manuring will always have two points of view, one special to the crop, the other to the soil; on good all-round soils, fertile loams and the like, the composition of the fertiliser employed will be dictated by the nature of the crop; on the more specialised soils, as on the pure sands, heavy clays or peats, it will depend primarily upon the soil.

It is on these special soils that Liebig's "law of the minimum" is chiefly seen to operate; if any one of the elements necessary to a plant's nutrition is deficient then it is the supply of that particular substance which will determine the yield of the crop, however abundant the other elements may be. This law of the minimum may, indeed, be extended more widely to include other factors than the supply of fertilisers; temperature, water-supply, the texture of the soil, are all "limiting factors" in the nutrition of the plant, any one of which may so determine its growth that variations in the other factors are of no account. Thus it is not uncommonly seen that in an exceptionally dry season a series of experimental plots may show little or no variation in the results

due to the different manures; on each plot the crop grows as far as the limited water supply will allow it, and for this small development there is in each case an excess of all kinds of plant food to be obtained from the soil. In a wetter season of abundant growth it may be the supply of potash or phosphoric acid gives out on one or other plot, whereupon that becomes the limiting factor determining the yield.

To summarise then the position we have reached—a fertiliser must contain one or more of the three substances, nitrogen, phosphoric acid, and potash, which alone among the various elements necessary to the nutrition of the plant cannot be supplied by cultivated soils in amounts sufficient for profitable crop production. The soils do contain these substances in comparatively enormous quantities, but the distinguishing feature of a fertiliser which makes it effective when supplied in quantities comparable with those removed by the crop, is its "availability."

CHINESE IMITATIONS OF HARD STONES.

By W. L. Hillburgh.

Hard stones are imitated by the Chinese in three entirely different ways; by the use of glass, which is comparatively soft and easily scratched; by the treatment of a true hard stone to appear other than it really is; and by the use or treatment of a softer stone. Such imitations are frequently so cleverly imitated as to deceive even experts, Chinese as well as European, who, not having before come into contact with certain of them, fail to apply all the necessary tests.

Glass is used particularly for the reproduction of jade, white, green, or variegated, and sometimes so cleverly that even close optical inspection hardly suffices, and the specimen must be handled before its character is ascertainable. Many small objects are made of this imitation jade, principally thumb and finger rings, buttons, snuff bottles and their stoppers, and the like.

True jade has a certain waxy appearance, which is seldom seen in glass, and a greasy feel which glass lacks. It is harder than glass, and easily scratches it; in equal bulk it is heavier; and, like most hard stones, having a greater heat conductivity, feels colder at ordinary temperatures. Glass often contains minute bubbles in its interior, which appear as pin holes on its surface when ground.

A stone imitated in a very clever manner is agate, particularly the translucent brownish or greyish variety, in which dark brown spots and patches are included. Agate glass is frequently used for snuff bottles, and may generally be detected, without further test, by an examination of the bottom of the bottle, which, if of glass, usually shows several streaks approaching a point, an appearance not present in true agate. Another variety of agate or onyx, which is sometimes copied in conglomerate glass, for snuff bottles, consist of irregular masses and streaks of colour, indiscriminately mixed.

Ordinary crystal is imitated by a clear glass, and certain coloured and fissured varieties by coloured glasses. These fissured varieties are generally pink or blue, and are produced by crackling and re-heating the glass; their colour is in the body of the material, and not within the fissures, as in artificially coloured quartzes. Such glasses, and imitations of the valuable translucent green jade and other precious stones, are used particularly for the stoppers of snuff bottles.

In connection with these imitations, an ingenious application of glass to the culture of artificial pearls may be noted. Pearly white glass beads are placed between the body and the valves of the bivalve which produces the remarkable shells, in which nodules, fish, images, &c., are embedded. These beads become coated with nacre, and, upon removal from the shells, are pearls which do not require piercing; such as were to be obtained seemed of bad colour, and to have a tendency to lose their coatings about the mouths of the openings.

There are several kinds of artificially-treated stones. Quartz is coloured pink, to imitate rose quartz, and blue, the colour being applied, it is said, by boiling. The innumerable cracks take up the dye, so that, if well done, the whole appears to be uniformly tinted, until closely examined, when the colour is seen to lie in varying quantities in certain planes about transparent stone.* This material, which is classed by some Chinese with the glasses, and not with hard stones, is used principally for stoppers for snuff bottles and for jewellery, but also for the bottles themselves, and occasionally for ornamental pieces of considerable size, though it is somewhat unsuited for elaboration in these latter, on account of the weakness due to the numerous fissures.

Similar in nature are personal ornaments, principally bangles, of white quartz, stained green or brown in portions, and belt-hooks stained in a layer, to represent a variety of cameo.

Imitations oftentimes difficult of detection, and made with intent to defraud, are produced by "backing" thin crystal, as in a snuff-bottle, with

* Since Roman times methods of artificially colouring stones by boiling them in various liquids have been employed by European jewellers, whilst at present the manufacture of artificially coloured agates, is largely practised in Germany. The German agates, however, differ from the Chinese quartzes in that their colour is taken up by pores, not by figures, in the stones, and appear to be naturally and uniformly distributed. Much information on European methods of artificially staining stones is to be found in C. W. King's "Nat. Hist. Gems and Decorative Stones," and "Nat. Hist. Precious Stones, Metals, and Gems."

a transparent colour, making the ordinary crystal appear as a more valuable variety. A crystal snuff-bottle for example, is painted within with amethyst colour, which is then fixed so that it is difficult to remove. To all ordinary appearances the bottle is of amethyst, and, since crystal and amethyst differ only in their colouring, it answers the usual tests. If, however, such a bottle be held properly to the light, certain portions of it, notably the neck and bottom, or a design in relief, where reflections and refractions of the applied wash do not appear, show in their true colours. Generally the interior of the bottle is left unpolished, to give a hold for the wash, so that if the colour has been carelessly applied it shows, on close examination, in a number of very small points, like stippling. Smoky crystal and rose-tinted crystal are imitated in a like manner.

Small cavities in jade or quartz stones are sometimes so carefully filled with a waxy composition, of the proper colour, that the new surfaces appear to be those of imperfect portions of the original material. The filling substances becomes more noticeable when old, but can always be detected by optical examination, followed by testing with a pin point or a knife.

False cameos are occasionally made by fastening a piece of agate to an agate ground work of a different colour, the attached part being used to conceal a defect in, or an injury to, the material of the ground.

Objects of white jade are imitated in a white serpentine, which, though it takes neither the polish nor the rich lustre of true jade appears, when cut, sufficiently like the latter to be mistaken for it by the inexperienced and even by mineralogists. It is sometimes sold by unscrupulous persons as jade, but since it can be scratched with a knife is readily exposed.

Lapis lazuli is counterfeited by soapstone coloured blue by painting or (so it has been said) by staining. The execution of the painted specimens examined seemed to be very crude, and their material easily recognisable without the necessity of testing its hardness; they resembled rather genuine lapis lazuli which had been exposed to fire than the unburnt brilliant variety. According to King* the Chinese make imitations of large brightly-coloured agates by staining thin plates of alabaster.

* C. W. King, "Nat. Hist. Precious Stones, Metals, and Gems," Lond. 1865, p. 417.

THE TRADE OF INDIA, 1905-6.
III.

Customs Revenue.

The net revenue derived from Indian Customs duties in the year under review increased by 2·7 per cent. Eighteen of the articles on which duty is leviable yielded 82½ per cent. of the total revenue, and examination of the whole list shews that, although the Indian tariff comprises a lengthy tale of dutiable articles, there are comparatively only a few on which individually any revenue of importance is collected. These are spirits, grey piece goods (unbleached), sugar, piece goods (coloured), petroleum, white piece goods (bleached), silver and other metals, in the order named. On these the duties realised approached three-fourths of the above mentioned total.

The import rate of duty on cotton goods is 3½ per cent., *ad valorem*, and the total duty realised thereon in 1904-6 amounted to over 132 lakhs of rupees, or 26½ per cent. of the whole Customs revenue. On most classes of iron and steel the rate of duty is only 1 per cent. On nearly all other *ad valorem* dutiable articles the rate is 5 per cent.

The export tariff schedule is limited to rice and rice flour, and in these there was a fall of 12½ per cent., the decline corresponding of course with the decline in the exports of wheat. There is also what is called a tea cess, at the rate of a quarter of a pie, or the twelfth part of a farthing per pound on all tea the produce of India and exported abroad. The proceeds are paid to a committee to promote the consumption of Indian tea. The total collected in 1905-06 was over 3·11 lakhs of rupees.

Balance of Trade.

The excess of exports over imports, including treasure and Government transactions as well as merchandise, was 33½ lakhs of rupees, this being a very considerable increase over the figures six years ago. Some addition has to be made to this excess, in respect of unregistered trade, such as the goods conveyed away by native craft from the ports in the Native States on the west coast of India to Persia, Arabia, and Ceylon, as well as in respect of the value of the large re-exports of pearls from Bombay, mostly sent away by letter post. There is also a large excess of exports to be taken into account as regards the trade passing through the French Settlements, and a small and fluctuating amount in respect of the Portuguese Settlements. Mr. Noel Paton, however, reminds us that the exports of Government stores at the time of the South African war and the Somaliland expedition unduly swell the total exports from India, and that they are imperfectly recorded, seeing that there is no obligation on the part of the officials concerned in the export of those stores to pass them through the Customs.

Gold and Silver.

The value of the imports, exports, and net imports of gold and of silver present some curious features, and differ from the figures in the summary at the beginning of the report in that the former exclude and the latter include Government transactions in bullion.

Imported gold declined from 2,181 to 1,475 lakhs, while the exports increased from 1,210 to 1,429 lakhs of rupees. There was also production of gold of 358 lakhs worth within India itself. During the year there was a strong demand for gold in Japan and America, and this was contributed to by the

new arrangement under which gold destined for the Gold Reserve Fund or Gold Standard Fund is shipped directly from the country of production to London. Taking no account of what was mined in India the net imports of gold dropped from 970 to 45 lakhs, but adding the production the net addition to the stock of gold amounted to 404½ lakhs of rupees.

As to silver we are not informed in the report what was the value of the amount imported by Government but it must have been very large to have so considerably affected the net imports mentioned in the summary. The total imports of the metal slightly declined and the exports declined to 117 lakhs, a figure lower than that of any year since 1885-86. The net imports thus reached the entirely unprecedented total of 1572·3 lakhs.

Trade according to Countries and Shipping Trade.

Viewing the trade with countries for the year, the United Kingdom is of course first with 41·3, as against 41 8 per cent. in the previous year. Considering, though, the increasing facilities for direct shipment, the steadiness of the percentage seems to give cause for satisfaction. Next to the United Kingdom comes China, whose figures are of course largely affected by the exceptional circumstances of the opium trade. Germany takes the third place, her share of the trade having steadily increased from 9¾ lakhs' worth in 1902-3 to close on 20 lakhs in 1905-6. Then follow the United States, France, Japan, Belgium, and ten minor countries, Russia coming last of all.

We turn now to the important item of shipping. While the net increase in the value of imports and exports of merchandise in 1905-6 amounted to over £7,000,000 sterling, there was a decline in the tonnage of shipping entered and cleared at Indian ports, of about 9·25 per cent. The figures for 1904-05 were, however, abnormally large, and those of the later year indicate a return to the normal rate of progress. The steam tonnage was 97·4 of the total tonnage, and the average tonnage per steamer increased from 2,118 to 2,150 tons. These features are in strict accordance with the general laws, which are of course familiar to all students of shipping statistics. Viewing the figures from the point of nationality, it is significant to observe that, while English vessels enjoy an enormous preponderance, 81·3 per cent. of the total tonnage, they actually declined in number during the years 1905-06 from 5,683 to 4,938. On the other hand, the number of German vessels has been gradually and steadily creeping up from 270, in 1901-2, to 387 in 1905-6. After Germany follow Austria, Hungary, Norway, France, and Italy.

Frontier Trade.

The subject of Indian frontier trade is gradually coming to the front. It is a small matter naturally compared to the seaborne trade, but it displays steady progress, having increased by 177 per cent. since 1878-79.

The Quetta-Nushki Railway has now been opened, and it is reasonable to hope that with the greater facilities afforded by the daily service of trains since April last, trade will improve. There has been a steady, though small, increase in both imports and exports during the last five years. The chief imports from Seistan by this route consist of precious stones and pearls unset, while the exports were mainly cotton manufactures and indigo.

India's trade with Afghanistan, as a whole, has increased by 3 per cent. Fruit and nuts, animals (living), drugs and medicines, ghee, and raw wool follow in the order mentioned. There was an appreciable increase in the exports to Cabul, the principal articles being cotton piece goods, tea, cotton yarn, and manufactured leather. From Kandahar more than half the imports consists of raw wool, which rose from 18¾ to 23½ lakhs of rupees. Passing by Kashmir and Nepal, the trade with which calls for no special comment, we come to Tibet. The effect of the treaty of Lhassa of September, 1904, on the Indo-Tibetan trade has not yet been felt to any appreciable extent, although both imports (raw wool, borax, salt, horses, ponies, and mules) and exports (cotton piece goods and yarn, grain, coral, woollen manufactures, and metals) increased in about equal proportions. With Western China and Siam communications are as yet in too backward a condition to favour any marked development of trade.

C. E. D. Black.

NORWEGIAN CODFISH.

Codfish is caught in the winter and early spring on the northern and western coasts of Norway. When the boats and small steamers have entered harbour with their hauls, the entrails and heads are removed, and the fish, as a rule, sold to dealers, who take them on board vessels, or in packing houses close to the seashore. The fish is sold and bought by count, regardless of size. Expert splitters, placed at benches about two feet by five feet, and using a heavy, short, wide-bladed knife, make an incision along the lower or belly side, along the whole length of the fish, removing at the same time the upper half of the backbone. The fish is then, without washing, put down in even layers in the holds of vessels, or in packing houses, flesh side up. Over each layer is sprinkled salt, by an expert salter; the so called Trapani salt is preferred. Trapani salt is imported from Spain; it is a rather weak, small-grained, dull-coloured article, evaporated from sea water. About five barrels of this salt are used for every one thousand cod, and the net weight of each fish is about three and a-third pounds. The sizes of the fish vary greatly, and the salter has to use considerable judgment in the quantity of salt used. The American

Consul at Christiania says that when the desired number of fish, say 50,000 to 100,000, has been secured in one lot, the cargo is brought to some place where the rock formations, close to the seashore, are suitable for spreading such a large number for drying. As the cargo is unloaded, each fish is carefully washed in clean sea water. The black membranous skin on the insides of the fish is at the same time removed, likewise all blood contained in the bone cavities. Whenever the weather is suitable, clear windy weather being preferred, the fish is laid singly side by side on the flat rocks, and attended to by men, women, and even children. It is never exposed too long on the same side. Every two or three hours the fish are turned so that the flesh or lower side, and the upper skin-covered side, are alternately turned to the sun and wind. Every evening stacks are made of from fifty to one hundred fish, and the top covered with tarpaulins and weighted down with stones. In this manner the fish becomes solid and gains in appearance. In unfavourable weather, with fog and rain, it is left undisturbed in the stacks, but as soon as fine weather comes on it is again exposed. This is repeated till the fish is thoroughly cured and ready for shipment. The curing is done in the months of May and June, before warm weather sets in. It requires constant care and good judgment to bring the curing process to a satisfactory termination. If the fish is exposed too long to the sun it will scorch and turn dark; if there happens to be much foggy weather or rain its value will be much decreased by the influence of a certain fungus. To prevent this no remedy has as yet been discovered. Fish ready for export is either piled in the hold of ships in layers packed in bundles, each holding a certain weight, but of late years some of it is also shipped in tin-lined boxes when destined for a long voyage and warm climates. Codfish is also put up in Norway without the use of salt or any other preservative. Some of the fish is dried after simply removing the head and entrails. In this method, the fish are tied together by the tails in pairs, and hung on horizontal wooden poles resting on beams about eight feet above the ground. The fish preserved in this way are caught in Northern Norway during the regular fishing season, that is to say, from January to May. The article is known, in the trade, as stockfish, and is largely exported to Catholic countries. By ancient custom, this kind of fish is never taken down for shipment before June 12th each year; sometimes later, if the weather has been unfavourable. Cod and other fish is also air-dried the whole year round, after having first been split open the whole length, the only junction between the two halves being the tails and about an inch of fish above it. By the cut, the whole of the backbone is left on one side of the fish when split. Each fish is then strung on poles for drying in the same manner as the round, or stockfish. Among the fish prepared in the latter manner are cod, ling, coalfish, torsk, and some other varieties.

HOME INDUSTRIES.

Irish Railways.—It is generally believed to be the intention of the present Government to bring in a Bill for the purchase of the Irish railways; and the evidence taken by the Commission on Irish Railways, now sitting strengthens the preconceived opinion that without some sort of unification substantial modification of rates, and general acceleration of transit, are not possible. It is often said that railway rates are higher in Ireland than in other parts of the United Kingdom, and that the managers of the Irish railways treat the public badly, but this would not appear to be borne out by the facts. It is, of course, true that Ireland suffers from a multiplicity of railway companies, which means much unnecessary expenditure, but whilst the net receipts are much lower in Ireland than in Great Britain, and the costs of management much higher, yet, owing to the much smaller cost of construction, the average dividend from Irish railways is higher than in England or Scotland. And even the proportion of expenditure to receipts is lower than in England or Wales, though somewhat higher than in Scotland. Nor would it be true to say that, anyway of late years, the leading Irish railways have shrunk from large expenditure in opening up the country to tourist traffic, or to deny that they are co-operating in the general endeavour to improve the agricultural industries, by putting into operation schemes beneficial to the producer and trader. This has been admitted by official witnesses giving evidence before the Railway Commission, Mr. Robert Cantrell, for example, the representative of the Department of Agriculture and Technical Instruction, saying that the companies had readily adopted, as far as legally possible, the many proposals emanating from the department in connection with transit matters. As to opening up the country to the tourist the Irish railways, many of them, have of late, been exceptionally enterprising. The northern railways offer special facilities for transit to Carlingford Lough, the Giant's Causeway, and Portrush; the Dublin, Wicklow and Wexford exploit the Wicklow scenery; the Midland Great Western carry large numbers to Achill and the district about Recess; whilst the Great Southern and Western have special services to Killarney, and besides offering cheap fares, the companies have, of late, built a number of hotels where the accommodation was previously bad or insufficient. But if it be true, as it is, that the Irish railways are doing all that the yare legally entitled to do, it is equally true that they are doing less than the circumstances of the country require. Such service will only be possible under a practical scheme of unification which would permit of the railways being worked on economical principles. The Government that brought about this change would be conferring an immense benefit upon the languishing industries of Ireland, and it may be hoped that the recommendations of the Railway Commission will do something towards this end.

The Demand for Pig Iron.—In November, 1905, the total exports of pig iron from the United Kingdom amounted to 82,719 tons; in the same month of the present year they reached 182,046 tons. The increased demand has been general all over the Continent with the exception of Sweden, which last month took only 3,903 tons, as compared with 5,112 tons in November, 1905; but by far the greatest increase has been in the exports to Germany and the United States, the figures for the former country being 38,861 tons as compared with 15,952 tons in the corresponding month of last year, and for the latter 52,579 tons, as against only 11,179 tons in November, 1905. In the eleven months ended November, the exports of pig iron from the United Kingdom amounted to 581,233 tons, more than for the corresponding months of last year, but only 86,000 tons of it has been due to America. It is only very recently that the American demand has been considerable. The larger increase has been in German imports, due to the inability of Germany to supply her neighbours with German iron. Notwithstanding her furnace capacity, and her large employment of the basic process, Germany cannot supply the wants of her own steel makers. Both Germany and the United States have been compelled to come to the United Kingdom for hematite as well as for ordinary iron, and there is no likelihood of an early cessation of the demand. Home contracts for raw material are drawing to an end, and the tendency of prices is still upwards. The prices of finished product are advancing also, although the makers of shipbuilding materials are restrained by the depressed condition of the consuming industry. In the North the export demand has become so excessive that small smelters will soon be compelled to refuse all further foreign business unless they are willing to see their home customers stranded for want of raw material. It would be rash to attempt to predict when the demand from Germany and the United States, more especially the latter, will slacken. Meanwhile, to quote the *Statist*, the only reserve of iron in Europe seems to be the stock of 540,000 tons in the Middlesborough Warrant Stores, and nobody knows who actually holds that stock. It would be more satisfactory if the abnormal demand came from home requirements rather than the needs of Germany and the United States, assisted in much smaller degree, but still appreciably, by the increasing demands of Italy, Japan, and Canada, the export to Italy last month having risen—as compared with November, 1905—from 4,878 tons to 10,597 tons; to Japan from 2,789 tons to 6,549 tons; and to Canada from 5,893 tons to 15,754 tons.

The Working of the Coal Tax.—A Parliamentary paper, just issued, shows the extent to which the Exchequer benefited from the imposition of the coal tax, now repealed. The duty came into force in the middle of April, 1901, and ceased at the end of October last. Between these dates, 361,577,500 tons of coal were exported, of which 92,683,300 tons were bunker coal. The proportion of this export liable to duty was 223,066,900 tons, say 62 per cent., and the amount of tax collected was £11,125,100. The smallest sum received was in the initial period of 1901-2, when the rebates amounted to a considerable sum. The receipts from the tax were highest in 1905-6, when the tax yielded £2,184,000. The average for the five years works out at £1,934,400. The duty paid during the current year was £1,533,200, equivalent to £2,628,000 for the twelve months. It will be seen from these figures that the duty brought in a very considerable sum to the Exchequer. Opinions as to its effect upon the coal industry differ sharply, but it is certain that the German coal export trade benefited by it.

British Preference in Canada.—Some uneasiness has been caused by the tariff changes proposed by the Dominion Government. So far as the general tariff is concerned, British exporters do not complain. The new tariff abolishes the rigid 33⅓ preference in favour of British goods, and substitutes a more varied classification. The Canadian official view is that upon the whole the new schedule is slightly more favourable to Great Britain than the old one. The uneasiness is due to what is called the Intermediate Tariff, a new device which is intended to assist the Dominion Government in negotiating for reciprocity with protectionist countries, and averages 10 per cent. lower than the general tariff. Obviously if this Intermediate Tariff is to be applied, it may materially modify the preferential position of Great Britain; and assuming it is applied to imports from the United States, may have very wide reaching results. But if the view of the Dominion Minister of Marine is the correct one, and is adopted by the Legislature and the Government, this Intermediate Tariff will be inoperative in the direction from which there is the greatest danger. Mr. Fielding says that the Intermediate Tariff cannot apply to the United States, because it is governed by such favoured nation treaties as are binding on Canada, and as the United States does not enter into such arrangements, the Intermediate Tarift cannot be applied to it. The same argument would exclude Germany, whose trade with the Dominion at present is not very considerable, but which, under altered conditions, might grow to much larger dimensions. The most-favoured nation treaties in force are with countries from which Great Britain has little to fear. This official view is not generally accepted in Canada, where, rightly or wrongly, it is thought that the Intermediate Tariff is designed mainly as a basis for negotiation with the United States. That the export trade of the United States with Canada grows more rapidly than the British, notwithstanding the present preferential tariff in favour of the latter, is shown in the following figures, taken from the official monthly report of the Department of Trade and Commerce of Canada, just to hand:—

	Imports from Great Britain. Dols.	Imports from United States. Dols.
1904	25,934,295	72,218,401
1905	27,847,699	70,097,293
1906	32,745,296	83,420,899

These figures are for the five months ended August 31, 1906, and show that while in the three years the increase of British exports to Canada has been between 6,000,000 and 7,000,000 dollars, those from the United States have increased by over eleven million dollars.

Cornish Mines.— Attention was directed some time ago in these Notes to the revival of the Cornish mining industry, and since then there have been further and considerable developments. There would seem to be no sufficient reason why Cornwall should not again become a great ore-producing county. A century ago, the Cornish annual output of copper was worth roughly one and a quarter million sterling, and it must be remembered that the output of copper ceased not because there was no more copper to be got, but because prices fell to a level, that prevented its profitable extraction. In the palmy days of the industry, the price of copper was about £140 per ton, then it fell to £100, and afterwards to a much lower figure. Attention was then turned to tin, and there was a similar experience, and when tin fell to something like £30 per ton few of the mines were able to continue working at a profit. But now prices have gone up again to the profitable level, and are likely to continue there. Moreover, an improved system of working will largely reduce expenses. There are of course difficulties in the way of re-opening many of the mines, the most serious being the unwatering, but they are not insuperable, or, perhaps, very formidable, while the abolition of the cost book system, the use of up-to-date machinery, the establishment of smelting works at the mines themselves, and the general adoption of modern methods, cannot fail to reduce working expenses, and go far to ensure a renewed period of prosperity for copper and tin mining in Cornwall.

GENERAL NOTES.

ST. PIERRE AND MIQUÉLON.—In reporting upon the North American colonies of France, Mr. Consul Woodhouse points out the desirability of direct and regular communication between the islands of Newfoundland. At present the only mail and passenger service that exists is maintained by a small passenger steamer, under the French flag, which makes a round to North Sydney, Halifax, and back again once a fortnight. There is no direct means of communication, although the Newfoundland coastal mail steamers plying between St. John's and Port-aux-Basques pass by St. Pierre every trip. The French authorities, says Mr. Woodhouse, would willingly waive all harbour and light dues, pay for transport of mails, and grant all the facilities in their power, if the steamers would call regularly. Newfoundland would benefit by securing a market for its produce, and St. Pierre by obtaining the ordinary necessities of life at lower rates. Unfortunately, the French islands are suffering much from bad fishing seasons, only about half the number of schooners being fitted out last season as compared with that of 1902, and the two islands are entirely dependent on the fisheries.

UNITED STATES CEMENT COMBINATION.—In a recent report issued by the United States Department of Commerce and Labour, it is stated that a bulletin of the Geographical Survey calls attention to the fact that there is a noticeable concentration of interests in the cement industry, and that this will probably become more accentuated year by year. The 88 plants in existence in 1905 were owned by 78 companies, and several of these nominally independent companies are closely connected by ownership. It is stated, however, that good raw materials are so widely distributed in the United States that there is hardly a county which could not produce Portland cement if prices were forced high enough. The only limitation now on the erection of cement plants is in the fact that the great cost makes the venture prohibitive for the individual or the small firm. The cement industry is at present in a more concentrated condition than was the iron and steel industry at the date of the formation of the United States Steel Corporation. The total authorised capital of all the American Portland cement companies now in operation will fall between the limits of £22,000,000 and £25,000,000. The bulletin states that this capitalisation cannot be considered excessive in view of the fact that it would cost probably from £15,000,000 to £17,000,000 to replace the plants now in existence.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

JANUARY 16, 1907.—Adjourned Discussion on Mr. J. W. GORDON's paper, on "Patent-law Reform." SIR WILLIAM PREECE, K.C.B., F.R.S., will preside.

JANUARY 23.—"The Isthmus of Panama." By PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

JANUARY 30.— "Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

Dates to be hereafter announced:—

"The Principles and Practice of Insurance, and their modern Developments." By THOMAS EMLEY YOUNG, B.A., Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association.

"Smoke Prevention in Factories." By JOHN B. C. KERSHAW, F.I.C.

"The Underground Water Supply of the Thames Basin." By CLAYTON BEADLE.

"Engraving and Photogravure." By. J. CRAIG ANNAN.

"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc.

"Cold Storage and Food Supply." By HAL WILLIAMS.

"Modern Typewriters and Accessories." By ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts.

"Motor Omnibuses." By LORD MONTAGU OF BEAULIEU.

"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S.

"Hungarian Arts, Home Home Industries and Commerce." By LOUIS FELBERMAN.

"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

JANUARY 24.—"The Bhils of Western India." By CAPTAIN E. BARNES, Indian Political Department. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

FEBRUARY 14.—"The Practical Side of Famine in India." By SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces.

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I.. LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

JANUARY 15.—"The Progress of the Uganda Protectorate." By GEORGE WILSON, C.B., Deputy Commissioner Uganda Protectorate. Brigadier-General SIR FREDERICK J. D. LUGARD, K.C.M.G., C.B., D.S.O., will preside.

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

FEBRUARY 19.—"Joinery and Furniture Making." By A. ROMNEY GREEN.

MARCH 19. —"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

January 28; February 4, 11.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S, "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

JUVENILE LECTURES.

Wednesday afternoons, January 2 and 9, 1907, at 5 o'clock.

"Perils and Adventures Underground." By BENNETT H. BROUGH.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 31...London Institution, Finsbury-circus, E.C., 4 p.m (Juvenile Lecture.) Mr. W. H. Garrison, "Volcanoes."

TUESDAY, JAN. 1..Royal Institution, Albemarle-street, W. 3 p.m. (Juvenile Lecture.) Mr. W. Duddell, "Signalling to a Distance—from Primitive Man to Radio-telegraphy." (Lecture III.)

WEDNESDAY, JAN. 2. SOCIETY OF ARTS, John-street, Adelphi, 5 p.m. (Juvenile Lecture.) Mr. Bennett Brough, "Perils and Adventures Underground." (Lecture I.)

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. W. H. Garrison, "The Fire Belt around the Globe."

THURSDAY, JAN. 3—Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Mr. W. Duddell, "Signalling to a Distance." (Lecture IV.)

FRIDAY, JAN. 4...London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. H. Garrison, "Earthquakes and Geysers."

SATURDAY, JAN. 5..Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Mr. W. Duddell, "Signalling from a Distance." (Lecture V.)

Journal of the Society of Arts.

No. 2,824. VOL. LV.

FRIDAY, JANUARY 4, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 9, 5 p.m. (Juvenile Lectures.) BENNETT H. BROUGH, "Perils and Adventures Underground." (Lecture II.)

Members requiring a ticket for this lecture should apply at once.

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

On Wednesday evening, January 2nd, Mr. Bennett H. Brough delivered the first lecture of his course, addressed to a juvenile audience, on "Perils and Adventures Underground." The lecturer dealt first with the importance of the subject in view of the enormous number of our countrymen engaged in mining work and the vast amount of British capital invested in the industry. In this country alone the value of the minerals raised annually was close upon a hundred million pounds, the results of the labour of nearly a million persons directly employed in their extraction.

The old story-tellers whose fancy peopled the earth with giants and dragons, the air with fairies and witches on broomsticks, and the waters with mermaids, created the gnomes to be the guardians of underground treasures. But science, which fought against ignorance in the earth above, had descended to the depths below, and had dashed the sceptre from the hands of the gnome king. Nowadays, although the miner did not suffer from the evil powers of the gnomes of fairy mythology, or even of "demons in the form of little black boys," said to have been seen by an English traveller in Hungarian mines, he had to face danger on all sides. The elements—earth, air, fire and water—all conspired against him. Earth threatened him with falls of rock, air when it was mixed with poisonous gases, fire when he was blasting rock with explosives, and water with inundations. This constant exposure to danger had given miners wonderful quickness in dealing with emergencies, and great bravery in facing perils; and their heroic conduct in trying to rescue comrades had never been surpassed on any field of battle.

Investors would agree that mining was, at best, a very risky business; and examples were given of the part that chance had played in the discovery of mineral treasures, the stories being told of the discovery of gold in California, of tellurium ore in Colorado, of coal in Saxony, of diamonds at Kimberley, of the Comstock lode in Nevada, of the Klondyke goldfields, and of the old Spanish workings at the Darien gold mine in Colombia.

The various operations of mining were described, and the dangers against which the miner had to contend were enumerated. The principal source of accidents was due to falls of roof; and the need for carefully fixing timber props was urged. Accidents in lowering men down shafts were described, and reference was made to the terrible catastrophe on October 9th last at the Simmer and Jack East gold mine, when owing to the breaking of the steel winding rope, 23 Chinese miners were dashed to the bottom of the shaft, 1,200 feet below. In order to safeguard against such accidents, safety-catches had been invented, and their construction was explained by the aid of models. The dangers attaching to the use of explosives were pointed out, and the advantages to be gained from the use of electric firing machines, and of bobbinite and other flameless explosives were practically shown. Accidents in haulage operations and in the use of machinery underground received attention, and the continuous improvement in mining conditions since the Royal Commission of 1842, which led to the prohibition of the employment underground of women and of boys under ten years of age, was traced.

In illustration of the lecture, porcelain figures of gnomes were lent by E. Wahliss, 88, Oxford-street, W., electric blasting apparatus by John Davis and Son, Ltd., Derby, explosives by Curtis and Harvey, Ltd., 3, Gracechurch-street, E.C., and models and diagrams by the Board of Education.

The second lecture will be delivered on Wednesday next, 9th inst., at 5 p.m.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ARTIFICIAL FERTILISERS: THEIR NATURE AND FUNCTION.

By A. D. Hall, M.A.,
Director of the Rothamsted Experimental Station, Lawes Agricultural Trust.

Lecture II.—Delivered November 26.

The Supply of Nitrogen to the Plant.

In taking up the detailed study of fertilisers it is natural to begin with those containing nitrogen: not only is it the most important fertilising element, for it both costs more per pound and returns more to the farmer for his investment than either phosphoric acid or potash, but also it differs from the others in that plants live habitually in contact with a vast unusable store of it. Since plants live in an atmosphere four-fifths of which consists of elementary nitrogen it is perhaps necessary to justify a little the statement made in my first lecture that they only obtain the nitrogen they require in a combined form by means of their roots. The form that the demonstration has taken may be seen in the water culture experiment which has already been illustrated; in the absence of combined nitrogen the development of the plant is very small. The same is true for cultures in sand, which are more comparable with natural conditions, and many experiments have been performed with the greatest care with plants thus growing in artificial soils supplied with a known amount of nitrogen. When the plants have come to the full term of their growth the nitrogen they contain is found to be exactly balanced by the amount of the same element which has been removed from the soil. And if objection be made that such plants are enfeebled by the unnatural conditions, so that they have lost their power to bring nitrogen into combination —to "fix" it, in current language—there are many other types of experiment which render such criticism invalid. For example, Hellriegel performed a long series of experiments with different plants which showed, up to a point, that the amount of growth was very closely proportional to the amount of nitrogen supplied in a combined form when there was a sufficiency of the other elements of plant food present. This would not be the case were the plant able to get any nitrogen for itself from the atmosphere. Again, to meet an early objection of Liebig and his followers, in the Rothamsted experiments upon leafy root crops, which still seemed unable to draw upon the nitrogen of the air though freely supplied with phosphoric acid and potash, to one plot there was supplied a very small amount of active nitrogenous manure, just to give the young plant a good start, whereupon it might be able to continue to feed upon the atmospheric nitrogen. But, as Table VIII. shows, the small addition of nitrogen only produced a small increase of crop, very fairly proportional to the much larger increase produced by a normal application of the same fertiliser.

TABLE VII.—Barley (Hellriegel and Wilfarth).

If then the yield of most of our field crops is, within the limits of experimental error, proportional to the amount of combined nitrogen they receive, it is necessary to conclude that they have drawn none from the atmosphere. The tenacity with which in the face of such evidence the opinion has been held that the leaf of the plant can obtain nitrogen as well as carbon from the atmosphere is due to the difficulty that is thus introduced of explaining how the world's original stock of combined nitrogen can have arisen. Assuming the

world to have cooled down from the state of incandescent gas, it must have started with all its nitrogen in the free gaseous state, yet as we see it to-day all the stock of combined nitrogen is of organic origin.

The circulatory process through which combined nitrogen is put is very plain. Animals can only use the highly organised compounds like the proteids; these they break down during their vital processes to simpler compounds like urea and the amides, which in turn are taken by plants to be built up once more into the proteid complexes. This is, however, only a circulation, subject to occasional losses by breakings down as far as elementary nitrogen; there is never any bringing of fresh elementary nitrogen into the account. The stocks of combined nitrogen that have been handed down from past ages all speak of the same organic circulation, never of fixation. Coal is but the *débris* of an extinct vegetation; nitrate of soda, the glorified result of the same decay processes which give rise to nitrate of potash in India and nitrate of lime in the old nitre beds. Virgin soils with their vast stores of nitrogenous humus are often looked upon as having gained nitrogen by the accumulation of long epochs of vegetable growth, but if plants cannot fix nitrogen there can have been no gain but only a circulation of the pre-existing combined stock. At first sight there seem no processes at work either to bring about the original combination or to repair the stock from time to time. Inorganic agencies are certainly trifling because nitrogen is a difficult element to bring into combination, so great an initial expenditure of energy is required to separate the atoms in the gaseous molecule. Electric sparks will bring about a combination of nitrogen and oxygen, and lightning flashes through the air have been invoked to account for the trace of nitric acid to be found in the atmosphere and in rain water. Such an origin, however, is still doubtful, for it has not been found possible to correlate variations in the nitric acid content of the rain with the frequency or otherwise of thunderstorms. Again, it has been supposed that during the evaporation of water there is always a slight combination of nitrogen with the elements of water to form ammonium nitrite, but more recent and refined experiments are against the existence of any such reaction.

There has, however, of late years been discovered one vital process capable of fixing nitrogen, which has probably been operative since the beginning of life on the earth, and this process is the property of certain groups of bacteria only. The history of nitrogen-fixing bacteria begins some thirty years ago with the resolution by Hellriegel and Wilfarth of the great outstanding difficulty in the theory that plants only make use of combined nitrogen. Though the demonstration in the laboratory of this opinion seemed perfect, and though in the main it was corroborated by field experiments, there was one group of plants—peas, beans, clover, and their allies—which seemed to derive little or no benefit from nitrogenous fertilisers and yet actually left the land richer in nitrogen after their growth, although in the crop removed there was an exceptional amount of nitrogen. That beans or vetches or lupins were the best preparation for a wheat crop was a commonplace of Roman agriculture, and the same observation became afterwards enshrined in that most fundamental of rotations, the Norfolk four-course system, in which wheat follows clover or beans. Hellriegel and Wilfarth found that leguminous plants did gather nitrogen from the atmosphere, and could, therefore, become wholly independent of nitrogenous manures; but this only took place when, by infection from the soil, certain characteristic nodules were formed upon the roots. These nodules were found to be colonies of a particular bacterium which seem to live symbiotically on the host plant, furnishing it with nitrogenous matter and deriving from it the carbohydate required for the fixation of nitrogen. As the fixation of nitrogen is a chemical process analogous to going up hill it requires a supply of energy from outside, which external source of energy the bacterium obtains by the oxidation of carbohydate in some form or other. The particular bacterium living in symbiosis with the leguminous plants seems to be highly specialised and has not been transferred to other non-leguminous plants; only with some difficulty it has been made to grow and to fix nitrogen when living alone and no longer in association with its host. With increasing knowledge of the methods of handling this organism, it seems probable that by cultivation we shall be able to obtain races showing variations in their power of fixing nitrogen, but how long they will retain this greater or lesser virulence after inoculation back to the leguminous plant is still uncertain.

The leguminous plants form then by their association with nitrogen-fixing bacteria, one considerable natural source of combined

nitrogen, and how effective they can be in accumulating fertilising matter in the soil may be judged from the accompanying Table showing the results of some of the Rothamsted experiments upon leguminous crops.

The only practical limitation to the gathering of nitrogen by this method lies in the difficulty that is found in growing leguminous crops frequently on the same land. Although, as we have seen, it is possible to grow wheat year after year for more than half a century and maintain the yield if the appropriate manures are employed, on few soils can clover be grown with success more frequently than once in four and even once in seven years. As the farmer says, the land becomes "clover sick," and though the clover seed germinates and grows for a time the constitution of the plant is so weak, that it almost inevitably succumbs during the winter to an attack of fungoid or other disease. The determining cause of this weakness of constitution which lies at the back of "clover sickness" is still unknown, but preventing as it does the more extended use of these nitrogen collecting crops it would be of serious economic importance to find the cause and a remedy.

More recently, however, other bacteria have been discovered in the soil which are capable of fixing free atmospheric nitrogen without association with any host plant, provided they are supplied with some carbohydrate, from the oxidation of which they derive the energy necessary to bring the nitrogen into combination. Of these bacteria the best known and probably the most effective is a large organism, first examined by Beijerinck in Holland, and called by him *Azotobacter chroococcum.* It is widely distributed in cultivated soils both in Europe and America, and although I failed to detect it in the arid soils from the high veldt or the Karoo in South Africa, yet I obtained similar though perhaps slightly varying bacteria from cultivated soils in tropical East Africa and in Egypt. It appears to be only active when there is some calcium carbonate in the soil, possibly because in its oxidising reaction certain acids are produced which must be neutralised before its activity will continue. Roughly speaking, its action is to oxidise carbohydrates to carbon dioxide and water, forming as bye-products certain organic acids, *e.g.*, butyric, and some dark brown humus (whence the name "chroococcum"), and incidentally bringing a certain amount of nitrogen into combination, not more, however, under the most favourable laboratory conditions than 1 to 2 per cent. of the carbohydrate consumed. It is, however, extremely probable that we may look to this organism and its allies as the origin of the continued accumulation of nitrogen in such rich virgin soils as the black soils of the Russian Steppes or of Manitoba. As long as these lands were uncultivated the annual fall of the leaf and dying down of the summer vegetation furnished the conditions necessary for the activity of the *azotobacter*. The carbohydate - containing material thus returned to the soil provides the organism with its necessary food supply by the oxidation of which it gains energy to fix the atmospheric nitrogen. In cultivated soils where the crop is removed the action is almost brought to a standstill, as may be seen in the steady loss of nitrogen from the arable soils at Rothamsted during the fifty years they have been cropped without any extraneous nitrogen supply. Only when land is laid down to grass is there a sufficient amount of carbohydate *débris* returned to the soil to allow of the gain of enough nitrogen to be evident in practice. A good example of the natural accumulation of combined nitrogen may be seen in two pieces of land at Rothamsted, which for the last twenty-five years have been allowed to run wild and assume a natural prairie condition of self-sown weeds and grasses that are never taken away but left to rot where they died down. Samples of the soil had been taken at the beginning of the period, and by

comparing them with more recently taken samples it has been possible to detect a very considerabe fixation of nitrogen, amounting in the most favourable case to nearly one hundred pounds of nitrogen per acre per annum.

The second similar piece of land shows a much lower result and this is correlated with the absence of carbonate of lime in the soil of that plot and a corresponding absence of the *azotobacter* organism.

It is too early yet to speculate freely on the work of the various nitrogen-fixing bacteria; we may, however, confidently attribute to their action both the current stock of combined nitrogen in the world and the main source of its renewal in the future.

Attempts have already been made to raise these nitrogen-fixing bacteria artificially, particularly those associated with leguminous plants, and by introducing them into soil that was lacking or poorly supplied with them, to render it capable of self-enrichment in this most natural manner. Such cultures are, in fact, sold commercially at the present time and have in some cases been somewhat unscrupulously boomed as dispensing with the need for nitrogenous fertilisers. Undoubtedly cases may be quoted where the use of these pure cultures of nodule-forming bacteria has been of great service, generally on newly-reclaimed soils which have thus become for the first time capable of carrying a legumiuous crop. But in old cultivated soils the organism is already present, and sufficient evidence is not yet forthcoming to show that the new introductions have had any effect; certainly the results obtained in the British Isles are almost wholly negative. Doubtless, the useful soil bacteria will be domesticated, improved, and made more effective just as our flocks and herds have been tamed and developed, while the useless ones will be stamped out as vermin; but at the present time we cannot be satisfied that any improved race of bacteria introduced artificially into the soil has managed to persist and get a real footing in face of the competition of the enormous natural bacterial flora already existing there. So the picture of the farmer carrying the manure for a field in his waistcoat pocket and applying it with a hypodermic syringe, is still a vision of the future.

These natural processes for the recuperation of our stock of combined nitrogen have, during the last year or two, been supplemented by one or two manufacturing processes of great interest in themselves, which are on the point of becoming factors of importance in the fertiliser market.

Speaking broadly, there are two ways of bringing free nitrogen gas into combination; first, at extremely high temperatures, such as are attained in the electric arc or sparks, nitrogen will combine with oxygen to form various oxides from which with water, nitric acid will eventually result; secondly, nitrogen will combine with a few metals and allied bodies, again at high temperatures, to yield substances which under the action of water yield ammonia. It is this latter method which was first developed on a commercial scale by Professor Frank and Dr. Caro in Berlin. They did not exactly start with a metal but with calcium carbide, the substance now so well known as the source of acetylene for illumination. This body Frank and Caro found would combine readily with nitrogen gas at quite moderate temperatures, and the resulting substance, calcium cyanamide as it is called, or kalkstickstoff, will decompose under the action of water, yielding its nitrogen as ammonia and the calcium and carbon as calcium carbonate. In the manufacturing process the calcium carbide is first roughly ground and then heated in iron tubes through which a current of nitrogen gas is passed. The calcium carbide, which itself results from the reaction of a mixture of chalk and coke in the electric furnace, must either be purchased or manufactured by a preliminary process. The two reactions of forming the carbide and uniting it with nitrogen can indeed be carried out simultaneously, but this method has been abandoned in practice. The Italian company, which has now taken up the patents for the manufacture of calcium cyanamide, has established its factory alongside one of the great producers of calcium carbide at Piano d'Orte in the hills above Rome, where water-power can be obtained for the cheap generation of electricity. On theoretical grounds one electrical horse-power per annum should bring about the fixation of 772 kilogrammes of nitrogen, in practice 300-330 have been attained. The nitrogen gas is obtained by passing a current of air over red-hot copper, the copper oxide formed being afterwards reduced to the metallic state again by sending over it a current of coal-gas while it is still hot. More recently a process of obtaining nitrogen by frictional distillation from liquefied air has been employed. The resulting calcium cyanamide is a dark grey, heavy powder, slowly reacting with the moisture in the air and giving off certain

strongly smelling gases characteristic of calcium carbide itself. The normal product contains as much as 20 per cent. of nitrogen, the theoretical substance being $CaCN_2$ with 35 per cent. of nitrogen. With superheated steam it reacts to produce ammonia and calcium carbonates in accordance with the equation—

$$CaCN_2 + 3\ H_2O = 2NH_3 + 3\ CaCO_3.$$

With acids the reaction is rather violent and various highly nitrogenous bodies are produced. It is the first reaction, however, which is supposed to take place when calcium cyanamide is applied to the soil: it should change slowly into ammonia, which will be arrested by the soil, and calcium carbonate. It has been shown, however, by Löhnis, that the reaction with water alone is slow and not particularly effective, but that certain soil bacteria are operative and bring about the change in practice. Löhnis's conclusions have been confirmed in the Rothamsted Laboratory, and it is certainly a remarkable fact that bacteria present in the soil should be capable of attacking so entirely novel a material. As a commercial fertiliser, calcium cyanamide has been subjected to a series of fairly conclusive trials which would show that on most soils it is not quite so effective as sulphate of ammonia supplying an equal amount of nitrogen. For example Table X shows the results of four

TABLE X.—ROTHAMSTED EXPERIMENTS WITH CALCIUM CYANAMIDE, 1905.

	Barley.		Mangels.

Sulphate of ammonia	37·5	24	23·5	10·0	27·9

trials at Rothamsted in 1905, mangels and barley being the crops under experiment. On soils poor in lime doubtless the cyanamide would give comparatively better results because then the carbonate of lime, which is the bye-product of the decomposition taking place in the soil, would itself be of considerable value. The Rothamsted soil, however, contains sufficient carbonate of lime to minimise the effect of this factor. The chief drawback to the practical employment of calcium cyanamide as a manure is its chemical activity and sensitiveness to the action of water. It must travel in air-tight drums, as it not only deteriorates in damp air but generates gases, some of which are dangerous and inflammable. It cannot be mixed with other manures; a mixture with superphosphate, in particular, gets unpleasantly hot, even on a small scale. It has, therefore, to be sown on the land alone, and it should be incorporated with the soil a week or two before any seed is sown. If left on the surface there will be loss of ammonia, and even in the soil the ammonia and other gases evolved at first are injurious to the germination of seed. For similar reasons it cannot be used as a top dressing. These difficulties in handling the material are likely to prove serious drawbacks to its use by the ordinary farmer, and it is a question whether it would not be wise for the manufacturers to push the process a stage further and actually turn out an ammonia compound. For example, it is probable that calcium cyanamide could easily be made to react with superphosphate to produce a double phosphate of calcium and ammonium, which would be a valuable manure of a type that farmers are familiar with, miscible also with nearly all other fertilisers.

The other method of bringing nitrogen into combination—that of effecting its union with oxygen at the temperature of the electric arc—has received considerable attention, and forms the base of at least two working processes. It will be remembered that when Sir William Crookes in 1898, in his British Association address, warned the world of the rapidly progressive exhaustion of its supplies of combined nitrogen, it was to the union of nitrogen with oxygen that he looked for the future supply of combined nitrogen for the wheat crop, and he showed experimentally how the two gases would burn together at a very high temperature. Not enough heat, however, is given out by the flame to bring more gas up to the ignition point, hence the flame is only continuous as long as external energy is poured in. The reaction which takes place is expressed by the equation—

$$N + O = NO - 21{\cdot}6\ K.$$

Energy to the extent of 21·6 Kalories are required to bring 14 grams of nitrogen into combination.

Calculating from the best results Lord Rayleigh had obtained in bringing nitrogen and oxygen into combination by the electric spark, Crookes decided that if electricity could be obtained at 1-17th of a penny per

Board of Trade unit, as it was expected would be the case at Niagara, then nitrate of soda could be made artificially at about £5 per ton.

Such an electrical process was installed at Niagara by Bradley and Lovejoy, who produced a number of arcs between platinum poles with a continuous current at a potential of 10,000 volts. The oxides of nitrogen generated were converted into nitric and nitrous acids by steam and more oxygen, and a mixture of sodium nitrite and nitrate was prepared for agricultural purposes. The installation, however, only ran for 15 months, for though considerable amounts of nitric acid were produced, technical difficulties in maintaining the apparatus in working order proved insuperable. More recently what promises to be a really working process has been devised by Professor Berkeland and is running on a commercial scale at Notodden in Norway. In the Berkeland-Eyde process an alternating current at about 5,000 volts is set to form an arc between U-shaped copper electrodes, which are hollow and kept cool by a current of water within. The electrodes are placed equatorially between the poles of a powerful electro-magnet which has the effect of causing the arc to spread out into a broad flat flame. Though the temperature of the arc-flame is calculated to be 2600° C. it is not particularly luminous; it may be looked at directly from a yard's distance.

Through the furnace in which this special arc is generated about 15,000 litres of air are blown per minute at gentle pressure and the issuing air contains about 1 per cent. of nitric oxide and is at a temperature of 600° to 700° C. It is cooled and then passes into two oxidising chambers where the combination of the nitric oxide with the oxygen of the uncombined air takes place, after which it passes into a series of five condensing towers. Down the fourth tower, which is filled with broken quartz, water trickles, and picks up enough of the nitrous gases to become 5 per cent. nitric acid at the bottom; this is pumped up and trickles down the third tower, the process being repeated until the liquid leaving the bottom of the first tower contains 50 per cent. of nitric acid. In the fifth and last tower the absorbing liquid is milk of lime, and the resulting mixture of solution of calcium nitrite and nitrate is treated with enough of the previously-formed nitric acid to convert it wholly into nitrate, the nitrous fumes evolved being led back into the oxidising chambers. The product is then concentrated until it solidifies as a material containing about 13 per cent. of nitrogen, or 75 per cent. of pure calcium nitrate. Owing to the hygroscopic nature of calcium nitrate, it is found better to introduce an excess of lime and manufacture a basic nitrate for agricultural purposes.

The present factory has three electric furnaces installed, each employing 500 kilowatts, and the production amounts to about 150 kilogrammes of nitrogen fixed per kilowatt year, or about one-fortieth of the maximum possible from the energy equation with which we started.

Professor Berkeland calculates that the cost of manufacturing calcium nitrate containing 13 per cent. of nitrogen is about £4 per ton, and that it can be sold at a profit at £8 a ton, which would be equivalent to nitrate of soda at about £10 a ton. The present factory at Notodden has been putting calcium nitrate on the market for about a year and a half, the rate of production now being about 100 tons per month. A new factory is being built which will generate about 30,000 horse-power, and contain larger furnaces, taking each 750 kilowatts, and when this is in operation it is expected the output will amount to a 1,000 tons per month. As a fertiliser there cannot be the least doubt that nitrate of lime will be just as valuable, nitrogen for nitrogen, as nitrate of soda. At Rothamsted a chemically prepared nitrate of lime has been used for two or three years for a special purpose on one of the mangel plots and it has given exactly equal results to the nitrate of soda plot alongside. Many field experiments have also been carried out with the electrical product in Norway during the last year or two, and have shown that the new material can be strictly valued against nitrate of soda on the basis of the nitrogen it contains. Indeed, on some soils it is likely to be more valuable, because, as will be shown in the next lecture, part at least of the lime base will be left behind in the soil as calcium carbonate. This will be an advantage in peaty soils and will also save clay soils from the peculiar wetness and stickiness which results from the employment of much nitrate of soda.

It will be observed that the commercial production of these two new manures which science promises to put very shortly at the service of the farmer, calcium cyanamide and calcium nitrate, is entirely dependent upon a cheap source of electric power; a cheapness which cannot be obtained when the electricity has to be generated by coal, but which is only attainable with water power costing practically

nothing beyond the interest on the capital sunk in the installation of turbines and dynamos. In this respect our country is always likely to be at a disadvantage, so that we must look to receive our supplies of these new nitrogenous fertilisers from countries which combine considerable elevations with an abundant rainfall. Indeed, in the British Islands the proprietor of a waterfall of any magnitude is in a somewhat delicate position, for should he wish to turn it into power for one of these purposes he is sure to find a strong body of public opinion arrayed against him, an opinion too which is generally capable of bringing a good deal of indirect pressure to bear.

Meantime, while these processes are being perfected and the price of the unit of nitrogen in fertilisers is being reduced until the nitrate of soda exporters have to struggle to sell their article at a profit at all, it is to be hoped that progress will also be made with the biological fixation of nitrogen. If clover sickness could be got rid of so as to enable the farmer to introduce what is after all much the most generally profitable leguminous crop more frequently into his rotation, if the nitrogen fixing bacteria in the soil could be given a freer play, and particularly if the nitrogen-wasting bacteria in the soil can be reduced, we shall go far towards rendering the farmer independent of any external nitrogenous fertiliser. It is not always realised how very wasteful of nitrogen our soil is; for example, of the nitrogen applied to the Rothamsted wheat plot as farmyard manure during the last fifty years only 21·6 per cent. has been recovered in the crop; where it has been applied to the mangel crop about 10 per cent. more has been recovered. The rest has either been permanently lost as free nitrogen gas or remains in the soil as compounds which will only be transformed into plant food with the utmost slowness. The nitrogenous compounds in the farmyard manure must be broken down and oxidised by bacteria before they are available by the plant. These figures show how imperfect the process is, because many of the soil bacteria are either wasters of or competitors for the nitrogen supplied as manure. Some recent experiments have shown that by partially sterilising a soil its powers of crop production are doubled or trebled, probably because the plant is relieved from the competition of soil bacteria wanting nitrogenous food for their own development. It is not too much to hope that in time these laboratory experiments will get translated into practice and the soil made a much more effective medium than it is at present.

However that may be, cheapened nitrogenous fertilisers will be of special service to British agriculture; we cannot compete when a crop has to be grown cheaply over a wide area of land, a paying wheat crop in this country must yield something like 40 bushels to the acre, and if the manure required to bring up our production to that average costs too much, it may not be possible to grow the crop at a profit either on a higher or a lower level of production.

INDIAN SECTION.

Thursday afternoon, December 13th, the RIGHT HON. LORD AMPTHILL, G.C.S.I., G.C.I.E., in the chair.

The CHAIRMAN, in introducing the author of the paper, said that Mr. Yusuf-Ali was a member of the Indian Civil Service, and that qualification ought to be a passport anywhere in the British Empire. Many present knew what it meant to be a member of that Service, but to the generality of Englishmen the members of the Indian Civil Service were unknown, except under one or other of two conditions. The first was that the civilians made themselves objectionable to the highest authorities; and the second was that the highest authorities made themselves objectionable to the civilians. He would not lend point to his remarks by doing anything so invidious as particularising, but he thought the audience agreed with him that that was the case. Besides being a member of the Indian Civil Service, Mr. Yusuf-Ali was also an Indian member of that Service. He hoped the audience realised what an amount of character, energy, and enterprise it meant for a young man of India to come over to this country, pursue his studies here, and enter into competition with Englishmen in order to get into the Indian Civil Service. Mr. Yusuf-Ali had done that. The author came from a part of India (the United Provinces) with which he (the Chairman) was not acquainted, so he could not speak of his service there, but he knew that Mr. Yusuf-Al had already made a name for himself in this country, and that he was a man of very exceptional literary ability. The fact that he gave up time when he was on furlough to read a paper of such an interesting nature spoke for itself. But, in addition to that, Mr. Yusuf-Ali had written a monograph on the subject of silk fabrics, which was published by the Government of India; an article on civic life in India, which appeared in the *Asiatic Quarterly Review;* and so versatile were his talents that he was able to write a criticism of Goethe in the *Contemporary Review.*

Nothing could be more welcome to Anglo-Indians than that an Indian member of the great public service which administered the vast dominion of India under the British Crown should come to England and of his own free will endeavour to give information about his fellow subjects, and generally to allow those present to make acquaintance with one of them, and through him to hear the views and ideas of his fellow countrymen.

The paper read was—

THE INDIAN MOHAMMEDANS: THEIR PAST, PRESENT, AND FUTURE.

By A. Yusuf-Ali, M.A., LL.M., I.C.S.

"The more I learn about the Mohammedans," said a recognised authority on Indian matters the other day, "the more I learn to respect them." If the British public could entertain a similar feeling for the Indian Mohammedans, they would find it a little easier to understand some of the controversies which vex the Indian atmosphere. They would also, I fear, feel a little less confidence in putting forward those cut and dried schemes which, like English furniture, make a splendid show in Tottenham Court Road, but are apt to warp in the exceedingly dry climate of the Indian hot weather. It is certain that an imperfect appreciation of the Indian Mohammedans is at the bottom of much of the misunderstanding that exists between them and the English, and between them and their Hindu fellow-subjects. Let us see if we can briefly review their past history, their present position, and their future prospects. In doing so let us hold in view not so much a narration of events as an appreciation of the moral factors which have made the Indian Mohammedans what they are, and which will doubtless operate in their attitude to future events.

The interest of the early Mohammedans in India was three-fold, viz.: commercial, missionary, and political. The ordinary assumption that it was purely and exclusively political, can be easily shown to rest on a fallacy. To some minds, nurtured on stories like that of "Alexander and the Robber," high politics seem always identified with pillage and brigandage. In their eyes no wars can be right even if they are just. But if the causes of the great movements in political history are examined and analysed, they will be found to be of enduring importance only if they are the visible embodiment of moral and economic forces, while they merely float and burst like bubbles if they are called forth by the ephemeral prejudices or passions of unthinking multitudes.

The commercial interest in India of the Arabs and other nations of Western Asia (including Egypt, if we may adopt the definition of Herodotus), dated from a time long anterior to the birth of Islam. The Egyptians had a considerable maritime commerce with India before their country fell under the influence of Greece and Rome. The Arabs of the Red Sea littoral were always intimately connected with Egypt, and doubtless learnt from that country (if they had not discovered it themselves) the secret of the monsoons and, therefore, of the navigation of the Indian Ocean. When Egypt fell into confusion, they became sole masters of the commerce and carrying trade of the East. The quest after spices, gems, and ivory cast a glamour round the names of Ceylon and India, and the name of India (Hind) is even found as a feminine personal name among Arab women in pre-Islamic poetry. The tradition that Adam's Peak in Ceylon was the place where our first parents set foot on their fall from the Garden of Eden, invested the island with something like sacred associations, and in later times we hear of the pilgrimage of Arabs to what they conceived to have been the cradle of the human race.

Such was the soil of ideas, in which, with the dawn of Islam, was sown a seed of greater vitality than any which had germinated before. The vision of Islam was the brotherhood of the world, the union of all in a universal and democratic Church and State. The missionary spirit was strong and fervid. Says the Koran xlii. 14:—

> "Summon them to the Faith, and walk righteously therein, following the law rather than their desires. Say—'I believe in all the Revelation that God has sent, and I am bidden to decide justly between you. God is our Lord and your Lord. We have our works, and ye have your works; between us and you let there be no strife. God will make us all one, and to Him shall we return.'"

It is uncertain whether the settlement of the Mappilas (Moplas) in Southern India owes its origin to missionary or to commercial motives. Their advent is dated back to the second century of the Hijra (eighth century A.D.), about the same time as the Arab conquest of Sindh in the north.* They still form

* T. W. Arnold: "The Preaching of Islam," p. 216; "The Tohfat-ul-Mujahedin," translated by M. J. Rowlandson.

an important Arab colony in the Tamil country. So completely have they assimilated themselves to their surroundings that they speak Tamil, read the Koran in that language, and are somewhat isolated from the rest of the Mohammedans of India. In the Khilafat of Mansur, and subsequently, several Arab missionary settlements were established, and their representatives now form well-knit and prosperous Nonconformist Muslim communities on the west coast of India.

The political dealings of the Mohammedans with India are better known, because the eye can follow the movements of the big battalions, whereas the still, small voice that inspires them requires delicately adjusted minds, like Marconigraph receivers, to perceive its ethereal promptings. In the Khilafat of Osman (643-55), Syria and Egypt already formed part of the Muslim Empire; and on the east Irák formed a frontier province, with the eyes of pro-consuls already watching for new worlds to conquer. The prospects, however, of a political extension in the east were not favourable. A man sent to the frontier of India returned with this report:—"The water is scarce, the fruits are poor, and the robbers are bold. If the troops sent are few they will be slain; if many, they will starve." The Khalifa asked whether he spoke accurately or poetically (*dichtung oder wahrheit?*); to which he replied that he spoke according to his knowledge.*

It was early in the eighth century of the Christian era that the first political foothold was obtained by the Mohammedans in India. A vigorous force of expansion was then pushing the outposts of the Arabian Empire in all directions. In 710 Khorasan was captured, and the first serious contact of the Mohammedans with the Tartars began. In 711, in the extreme west, Tarik crossed the Gates of Hercules into Spain, and built the strong fortress of Gibraltar. In 713 Mohammed ibn Kásim, or, as he is usually styled, Mohammed Kásim, captured the town of Multan, which was then included in Sindh. At that time, apparently, there were already some Muslims in the country. The *Chachnáma*, which is our great authority for the stirring story of the Arab conquest of Sindh, gives us incidentally a picture of the state of the country. The people were divided into many races and tribes, and the Jats and the Meds welcomed the conquerors. The castes of merchants, artisans, and agriculturists are found in full working order. The religion is a form of Buddhism, but the Brahmans assert their supremacy and are followed by the people. Heavy engines of war are brought up by the Musalmans, and their success is, among other causes, due to the possession of sea-power, with a base in the Persian Gulf. In fact, the expedition itself was rendered necessary because of piratical acts at the mouth of the Indus, which the Hindu princes had no power to suppress or control, and which preyed upon Muslim commerce with Ceylon.

The civil institutions established in Sindh were full of toleration and equity, and their story forms one of the brightest chapters in Muslim history. Mohammed Kásim's address to the Brahmans whom he appointed as revenue managers shows both political sagacity and something of those large views which afterwards blossomed out in Akbar. "Deal honestly," he says to the Brahmans, "between the people and the Sultan, and if distribution is required, make it with equity, and fix the revenue according to the ability to pay. Be in concord among yourselves, and oppose not each other so that the country may not be distressed."* This is not only the attitude of Mohammed Kásim himself, but also of Hajjáj, the Governor of Irák, whose agent he was in the expedition. Hajjaj in a letter of appreciation praises him "for your military conduct, and for the pains you have taken in protecting the people, ameliorating their condition, and managing the affairs of the government."†

Many mosques and schools were built after the occupation, and public functionaries appointed to administer the law and decide disputes. But there was a large measure of toleration granted to the Hindus. On their petition that the Hindu temple should be allowed to be repaired and their religious rites carried on as before, the following orders were passed:—

"They have been taken under our protection, and we cannot in any way stretch out our hands upon their lives and property. Permission is given to them to worship their gods. Nobody must be forbidden or prevented from following his own religion. They may live in their houses in whatever manner they like."‡

This was in the earliest days of Muslim dominion in India. The Arab power was firmly established in Sindh, but it soon became

isolated from the rest of the Saracen Empire. It should be noted that this dynasty was the only one in India which was established directly under the guidance and initiative of the central Khilafat. Shortly afterwards rival Khilafats were established in the east and in the west, and many internecine wars occurred among the Muslims themselves. Their power continued to increase, but more under separate groups or units than under a central recognised authority. The attention of Muslim merchants, travellers, missionaries, geographers, historians, scientific men, and men of letters, continued to be directed towards the moral, intellectual, and material wealth of India. A merchant named Sulaiman embarked on the Persian Gulf and made several voyages to India and China. He wrote a valuable account of his travels, which is one of our early sources of information on India as seen by the Mohammedans. This was about the year 851 A.D. Accounts of this kind must have been fashionable about that time, for they were collated and edited by literary men who had access to libraries and were able to co-ordinate and comment upon the knowledge obtained at first hand by travellers. Such an editor was Abu Zaid, who met the famous geographer and historian Mas'udi in the literary city of Basra about 916, and edited the merchant Sulaiman's "Travels" in the light of the further information which he received from that great master of Arab style.

So far we have been looking at Muslim civilisation as represented by the Arabs, among whom there was a many-sided activity and the traditions of an intimate contact with the civilisations of Western Asia and the Mediterranean, in other words, the highest civilisations to which the world had yet attained. With the opening of the eleventh century comes a new racial force into Islam as represented in India. The expansion of the Turks, a comely, vigorous, blunt, and honest race, with primitive virtues and primitive failings, from their pasture grounds in Central Asia, had been proceeding with varying fortunes for centuries. The adoption, by the soft Kalifas of Baghdad, of a Turkish body-guard, gave them a status in the counsels of Islam. Their gradual reception into Muslim communities, as slaves, as freedmen, as soldiers, as leaders and rulers, prepared the way for that pre-eminence which they subsequently established with unquestioned power after their reception bodily into the fold of Islam.

Mahmud of Ghazni was a product of the general Turkish advance which took the Muslim world by storm in the fifth century of the Hijra. Of Turkish descent on his father's side and Persian on his mother's, he had the inflexibility and the refinement which characterise the two races respectively, while the Afghan *milieu* in which he won his spurs and established his court left its traces in the narrow sectarianism and the love of greed of which he has been accused. Mahmud made periodical invasions of India, to the number of 13 or 14, between the years 1001 and 1030, with the triple object of obtaining military glory, compassing the destruction of idols, and carrying off the rich booty which he found in temples like those of Mathura and Somnath. His own city of Ghazni he adorned with a marble mosque to which he made gifts of lamps studded with gems, like those noble specimens of Saracenic art which form the wealth and glory of the Cairo Museum. A library and museum were also added to the attractions of the city, which drew to itself men of art and learning, historians and poets, from different parts of the Muslim world. Firdausi, the national poet of Persia, has made him immortal, not only for his generous love of poetry, but, in a contrary sense, for his ignoble avarice.

The justice he administered was stern and pure, and his ceaseless activity and conscientious discharge of his duties of kingship bring him into strong contrast with the inglorious and ease-loving potentates into whose weak hands had fallen the direction of the central authority in Islam. The chief fact that stands out in the internal politics of India is again the hopeless divisions of the people, and the implacable hatred with which the Raja of Kanauj helped in the destruction of the Raja of Delhi. An instructive commentary on Mahmud's victories is supplied by the patriotic verses of the Hindu bard Chand Bardai, whose intimate picture of the politics of the Delhi Raja's court supplies the much-needed corrective to the indiscriminate panegyrics of the professed historians of the reign of Mahmud the Iconoclast.

The invasion of Muhammad Kásim had been by sea; that of Mahmud and all subsequent Muslim invasions were through the passes of the north-west frontier of India. Afghanistan now becomes the stepping-stone to India. The Arab invasions had been made by generals obeying the orders of the Governors of Irák, whose power was subject to the juris

diction of the Khalifa himself. The local commanders had to refer many questions for decision to the stay-at-home authorities, who might or might not realise the difficulties of the local situation. A wrong decision might jeopardise thousands of lives, and undo the work of brilliant politicians and skilful soldiers, as, in fact, happened in the case of Muhammad Kásim himself. The invaders through Afghanistan came on their own account and were their own masters. They were, therefore, able to follow a strong and less vacillating policy, and they gradually settled in the country and built up the foundations of a fabric on which the modern superstructure of the Indian Empire rests.

It should be noted that subsequently to the Arab conquest India under Muslim rule never formed a part of the Muslim Khalifate, or any of the rival Muslim Khalifates, but was a separate and independent kingdom, with ecclesiastical pretensions of its own. Even Mahmud, who had strong ideas of loyalty to the ideal Muslim State, whose boundaries were conceived to be co-extensive with those of the Muslim Church, in practice departed widely from that conception. In his later career he sought and accomplished an expansion to the sea, and maintained a naval force, with which he policed the Indian Ocean, and claimed to guard the pilgrim routes and protect the pilgrims to Mecca. As an issue of independent coinage marks an assertion of independent sovereignty, so the claim to protect the pilgrims to the sacred cities of Arabia is tantamount to an assertion of independent sovereignty in a prince of Islam.

After the time of Mahmud of Ghazni there were many invasions and many Mohammedan dynasties in India. Their story forms a tedious record of wars, revolutions, rebellions, and family feuds. There were some strong or interesting figures standing out on the page of history, such as Sultana Razia Begam, who rode on horseback like a man and affected the style and title of Sultan; and pious kings, who never touched a pice from the public treasury, but maintained themselves, according to the Muslim ideal, by working at some private trade in the intervals of their State duties. But, apart from isolated instances, there were no men of broad views or great ideas who were able to leave their impress on the history and institutions of mankind at large until we come to the spacious times of the Great Moghals.

This period is well known to the average English reader, and it will not be necessary to enlarge upon it. Before we glance at the personality of Akbar, the greatest of the Moghals, let us for a moment place before our eyes a picture of what these Moghals were, who were destined to play so large a part in the history of India. In fact, the name "Moghal" is a misnomer; they should rather be called Chaghtai Turks. Fortunately we have materials for judging what manner of men they were, not only from the memoirs left by Bábar, the founder of the dynasty in India, but the intimate revelations of their inner life and domestic relationships left us from the facile and lively pen of one of their princesses. Within the last few years Mrs. Beveridge has published a Persian transcript and an admirable English translation of "Humáyun-náma," a memoir by the princess Gul-Badan. She was a daughter of Bábar and an aunt of Akbar, and lived through three great reigns to witness scenes of triumph and disaster, of reconquest and organisation. Her memoir was composed in Akbar's reign to serve as part of the materials for the history of that monarch and his house. The manuscript which has been published breaks off three years before Akbar's accession, and, therefore, it fails in its original purpose of informing us as to the inner history of her illustrious nephew. But with the delicate touch of a feminine hand she sketches for us the internal lineaments of the early Moghals and their domestic history as it affected public events, and she does it with such fidelity and in such detail that it brings home to us the inner life of the people among whom Akbar was born and bred.

They were a rosy-cheeked race, who came over with Bábar to conquer Hindustan. They were fond of gardens, canals, fruits, and even wine. They were hardy, and loved all field sports, but they also cultivated music, poetry, and letters. Their women appeared unveiled before men, and, indeed, were always mixed up in the highest affairs of State. The greatest deference was paid to aunts and women of an elder generation. Not only did Gul-Badan write verses herself, but her niece, Salima Sultan Begam, was an accomplished poetess, and collected a library, to which apparently a copy of all books had to be contributed, which had any currency in court circles. Here we may see the germs of the Copyright Acts, which in modern countries serve to keep their central libraries supplied with copies of all the publications that issue from the Press.

The scenes in the domestic circle were genial and sometimes full of incident.

When Bábar wins his splendid triumph in India, he sends presents to all the ladies left behind in Kabul, who have doubtless been watching events with the same keen zest with which Clytaemnestra in the play watches for the return of Agamemnon, but with far purer and worthier motives. The presents are not sent in the mass, to be scrambled for or divided by chance or seniority. Bábar himself makes out a careful list, and selects an individual present for each, not forgetting a touch of humour in the present to a little child. With the greediness of a little fellow he is expecting a great many *Ashrafis* (gold coins), but he is told that only one has been sent for him and he is to receive it blindfolded. All the Begams assemble in a solemn session, the boy is brought into their midst with his eyes tied up, and a single gold Ashrafi is hung round his neck—but what a weight? It is a lump of 30lbs. and he can scarcely carry it. Amidst much laughter his eyes are opened, and he finds that he is the lucky recipient of a special Ashrafi—or rather medal—struck for him by the kindly thought of his genial relative. It contains more gold than the number of Ashrafis which he would have dared to ask for himself, if it had been left to his choice. But the humour of it all and the special distinction which marks him out show how Bábar's thoughts dwelt on him, as they did indeed on each individual of his household, man, woman, or child, in the midst of a busy campaign.*

While I am on the subject of the Begam Gul-Badan, it may be of interest to give a few further instances of the part which Mohammedan women have played and are likely again to play in Mohammedan history. The instances are by no means as few as some people would probably suppose, who admit that Islam has great qualities, but say that it has not done justice to women. Some of the Prophet's most burning speeches relate to this very theme—justice and fair dealing to women. Indeed, some of the heroines of the early harvest of Islam did not need to be protected from the men—quite the contrary. The battle of the Yermouk, which decided the fate of Syria in favour of the Arabs, was won by the superb courage of the women. Thrice had the warriors of Islam hurled themselves against the Roman phalanx, and thrice had a remnant of them retreated, bleeding and broken. But the Arab women behind the ranks ever urged them to charge, and to charge again. Abu Sofyán was struck on the face with a tent-pole by a woman. In these circumstances retreat was impossible; they went forward, broke the phalanx which had come to look upon itself as impregnable, and won the field.* A similar story is told about the battle of Bokhara in the 90th year of the Hijra. Towards the end of the eighteenth century our own Nizam had a regiment of Amazons, the Zafar Paltan, which is said to have fought as well as the men.† I have already mentioned Sultana Razia Begam as a lady accomplished in affairs of State. An even more accomplished Princess was the great Nur Jahan Begam, the consort of Jahangir. While he was wasting his energies in drunken orgies, she was virtually ruler of the state, and her name appears on some of the coins. Indeed, Tavernier tells a pretty story (which as Mr. Stanley Lane Poole points out,‡ was probably a popular legend) that she designed and issued the famous Zodiacal Mohurs of Jahangir. She was as just and liberal to the poor as she was peerless in her beauty and accomplishments. Many a noble lady's formula for attars and perfumes at the present day in India is traditionally ascribed to Nur Jahán. All suffering found ready help at her hands.§

Nor must we forget the literary ladies. We have seen what were the accomplishments of Gul-Badan and her niece. Zaib-un-nisa, the daughter of Aurangzeb, wrote a commentary on the Koran, and a volume of poems in Persian. To a later day belongs Gunna Begam, wife of Ghaziuddin, who founded the city of Ghaziuddin-nagar, which the railway authorities have re-christened Ghaziabad in the interests of brevity. She wrote Urdu verses, and her master in the art was no less a person than the poet Sauda. The story is that she was betrothed to the son of the Nawab Safdar Jang of Oudh, but eventually married the Wazir of the Empire,|| and the seeds of enmity thus sown created a permanent cleavage in politics which lasted till the dissolution of the

* This story is constructed out of a paragraph on p. 11a of the MS. as published by Mrs. Beveridge (Humayun-nama). I take Asas to be a little boy, perhaps a nephew or grand-nephew of Bábar. Mrs. Beveridge (p. 96, n. 4) takes Asas to be an old man and a servant. The words describing him are doubtful, but to me the story sounds more plausible if told of a boy.

Moghal Empire. Nor must we omit to mention the late Begam of Bhopal, whose literary accomplishments were exceptionally remarkable in a line in which literary gifts are hereditary. At the present day a great deal of literary talent lies buried behind the pardah, as I know from personal knowledge; but alas!

> Full many a gem of purest ray serene
> The dark unfathomed caves of ocean bear;
> Full many a flower is born to blush unseen,
> And waste its sweetness on the desert air.

In saying all this about Mohammedan women I am in no sense defending the abuses which have sapped the foundations of our social system and ended in the undoing not of women but of men. I have merely tried to point out the possibilities by means of concrete instances. The rising generation of Mohammedans are becoming more and more conscious of the abuses which shut out men from the most charming portion of mankind, those whose softening influence and gracious presence lend, as we find in Western lands, an added dignity and sweetness to life. Towards this ideal no family has worked with greater fidelity and success in India than that of the late Mr. Badruddin Tyabji, as all who were privileged to have an *entrée* to his family circle know and will remember with feelings akin to reverence.

The character of Akbar and the great forces for which he stands in Indian history are happily well known. Colonel Malleson's monograph on him, and Lord Tennyson's poem, "Akbar's Dream," have brought home his ambitions and his ideals to Englishmen who do not ordinarily seek inspiration in Indian history. A man of indomitable will and cool courage in the face of danger and difficulties, he used his successes for the furtherance of justice and equality amongst all men. Great in war, he was greater in peace. Fond of riding, hunting, and swimming, he studied a serious purpose in life, and marked out his time so as to hold a just balance between his multifarious interests. Under the influence of Abul Fazl and Faizi, he approached the deepest problems of man's intellectual and spiritual destiny, seeking wisdom not in one school or form of thought, but wherever he could find it. With the assistance of Todar Mal in revenue administration, and of Raja Jai Singh of Jaipur, the soldier-astronomer who fought his battles in far Kabul with a loyalty that does credit to both King and vassal, Akbar built up a sound system of administration which has commended itself to the judgment of the Imperial race of Britain. He, no doubt, had precursors in men like Sher Shah Pathan; we all build on other people's foundations. But his merit consisted in breathing into the whole system the soul of his personality. He grasped the cardinal principle of statecraft that no country can flourish in stability or permanence in which race fights against race and religious animosities have sway, but that the happiness of princes and peoples alike depends on unity of will, co-operation in self-sacrifice, and firm, unbounded loyalty to and confidence in all political ideals.

Akbar was not only great as an emperor: but he was a man of supreme humour. This is a point in his character to which sufficient justice has not been done. If half the popular stories that are current about his combats of wit with Bir Bal and others are apocryphal, the fact that so many *bon mots* are referred to Akbar shows what reputation he had for wit and geniality—and no sour man can possibly acquire such a reputation. The fact that so many of these jokes are against him only makes his toleration and good humour all the more pre-eminent. We have time for retailing only one. Akbar and Bir Bal once contended as to which of them could first overcome the other in conversation. A time was fixed in advance when the contest was to commence. Akbar primed himself with many wise saws and modern instances, knowing that the Hindu's memory was good and equal to many resources. When the time arrived, Akbar began. He made many sallies, and left many openings to lure his opponent on. But Bir Bal smiled placidly all the time and never said a word. At length Akbar said, dealing (as he thought) the hardest and straightest blow of all: "What can you do when you have to deal with a fool all the time?" Quick but quiet was Bir Bal's reply "In such a case," he said, "I should hold my tongue." Akbar ungrudgingly awarded him the prize of the contest.

The decline and fall of the Moghal Empire was due to many causes. Among Akbar's successors were strong and able men, but no one combined in himself the gift of that winning grace which made friends wherever he went, with that business ability, industry, and power of organisation, which could turn abstract ideas into concrete institutions. The jealousies and intrigues among the nobles and satraps were a strong

disintegrating force, which even Akbar could not always keep in subjection, but which broke out with destructive force when a strong policy was allied with intolerance and hatred of the Hindus. Above all, the mercenary army was allowed to fall into a state of indolence and disorganisation. The conquest had been achieved by strong men fighting for honour and glory · the empire was lost by weak men, who had no moral force of cohesion, though they never lacked personal courage. Mr. William Irvine has minutely investigated the military organisation of the Moghals, and this is his verdict: "The more I study the period the more I am convinced that military inefficiency was the principal, if not the sole, cause of the Empire's final collapse." *

In dealing with the present position of the Indian Mohammedans it is curious to observe the alternating favour and disfavour in which they have been held at different times by English opinion. Warren Hastings was catholic; he and the immediately succeeding generation of Anglo-Indians found much that was attractive in the Mohammedans, but, above all, they remembered their history and treated it with respect. After the Mutiny the Muslims fell under a cloud, undeservedly, because their premier chief, the Nizam, remained loyal to the core, and his great minister, Sir Salar Jang, practically kept the peace of the Deccan and of Central India. The feeling of suspicion against Mohammedan loyalty grew and grew, until it found a visible peg to fasten itself upon in the Wahabi propaganda, and culminated in a series of State trials from 1864 to 1871. In 1871 a miserable assassin struck down the English Chief Justice of Bengal on the steps of his own court, and in the state of excited feeling which then prevailed, that despicable act was fastened upon the community which he had disgraced. Calm observers, however, even then raised their voice against the injustice of attaching the stigma of an individual's crime to a whole community, whose antecedents and principles alike made such a crime peculiarly abhorrent to their moral and religious feelings. The law is reverenced by Mohammedans more than power and dignity. The late Prof. E. H. Palmer wrote an Urdu letter, pointing out the injustice of connecting such a crime with the feelings of the Mohammedan community, and the letter has been considered of sufficient importance to be published in Sir Walter Besant's "Life of Palmer." Sir William Hunter wrote a book with the significant title: "The Indian Mussulmans; are they Bound in Conscience to Rebel against the Queen?" Though he showed, on the whole, considerable sympathy with the Mohammedans, his views were so coloured with a misconception of the Mohammedan position that Sir Syed Ahmed Khan, of Aligarh, issued a rejoinder in the form of a review.

It is necessary, even at this day, to clear away the prejudices and misconceptions that attach to the Mohammedan position in connection with the Wahabi movement in India. The Indian apostle of the movement was Syed Ahmad of Bareli, who proclaimed a Jihád on the North-West Frontier in 1830, and was slain in 1831. This Syed Ahmad is in no way to be confounded with Sir Syed Ahmed Khan of Aligarh: the two men were as the poles apart. The Wahabi movement, in its earliest phases in India, had two aspects, the religious and the political.

The religious aspect was the more important of the two, and has proved to be the more permanent. In this aspect Wahabiism aimed at going back to the pristine simplicity of Islam, and sweeping away the accretions (such as the reverence shown to *tazias*, graves of ancestors, and saints) which have grown up in India. It also questioned the authority of interpreters of the Sacred Book, and would substitute a plain and simple appeal to the sources of the Law rather than to the network of glosses and analogical systems founded upon it. Put in this abstract way, it could justly be called the extreme Evangelical School in Islam, and has many of the characteristics of evangelical schools and revivals elsewhere. The spirit in which it was preached was that of hostility and an uncompromising attack on the existing order of things, and, therefore, the majority of Indian Mohammedans have always rejected it not only with scorn, but with something of the bitter rancour which is always called forth in religious controversies. In orthodox circles the name "Wahabi" became a term of abuse of even a deeper dye than "atheist" or "unbeliever."

The Wahabis as a religious sect in India are now of little importance, but their religious fervour has stirred the more orthodox schools to set their own houses in order. A number of new and liberal movements in Muslim theology have sprung up, of which as yet we are only seeing the early beginnings.

* William Irvine: "Army of the Indian Moghuls," p. 296.

The political aspect of Wahabiism never appealed to even an appreciable section of the Indian Mohammedans. It arose to a considerable extent from a misappreciation of the lessons to be learned from the twelve centuries of Mohammedan history which had already witnessed the rise and fall of many ideas. These ideas had failed, when translated into facts, to realise the ideal brotherhood of mankind. The further century which has since elapsed has added a more conclusive chapter of warnings against the thoughtless admission of the foul and tainted exhalations of rough-and-tumble politics to what should be the pure and serene atmosphere of religious peace and freedom. The original relation of Church and State at the birth of Islam was so close that the term Erastian has been applied to the Muslim idea of a Church; it would be more correct to say that the Muslim conception of a State was theocratic. This conception, unredeemed by the conditions which originally gave it reality, colours the schemes of all visionaries who do not learn wisdom from the lessons of history. The Khalifa, abstract and elective, is the counterpart of the Stoics' perfect man. What a cruel mockery then to dispute, on the religious plane, about the merits of a concrete embodiment which may be a negation of all the virtues postulated! Nor is the spectacle edifying when we see a man claiming to guide events which he does not understand, and hurling anathemas at the heads of other men of similar pretensions. It may be said that the collective conscience of Islam, though it has never formulated the doctrine in plain terms, has come to recognise that it tends to nobler spirituality in religion and greater strength in politics to conceive of the Mujtahid of the age, or several Mujtahids—to adopt a term which Akbar sought to apply to himself—as a personality distinct from the king or leader who uses judicial force for the suppression of anti-social force. This lesson has been specially, if unconsciously, brought home to the Indian Muslims. Even the small following which adopted the religious views of Wahabiism has practically repudiated its political corollaries. The sect has already been split into two. One portion openly and professedly reject the dangerous doctrines of Jihad, and the other hedge them round with so many qualifications that for practical purposes they may be considered now to hold the same political views as the rest of their co-religionists in India. These sects are principally found in Bengal, and the last census report of the province gives an excellent account of the practical trend of their doctrines. The orthodox schools (Sunni and Shiah) have always opposed the ultra-dogmatic tenets of Jihad, by means of numerous Fatwas and authoritative opinions.

I have lingered so long over this matter in order to show that there is nothing either in the religion or the history of the Indian Musalmans to prevent them from taking an honourable place as citizens in a free and progressive Empire. As to their relations with the British Government, they have tended more and more, within recent times, towards cordiality. His Highness the Nizam has always been a faithful ally of the British power, but never have his relations with that power been more cordial than they are now. The recent abolition of quarantine at Bombay for the pilgrimage to Mecca has brought solace to many a devout Muslim who had never heard and who never cared about the controversies raging in a certain portion of North-Eastern India. The statesmanlike reply of the Earl of Minto to the Simla deputation in October, and the speeches of Sir Arthur Lawley, have further helped forward the *rapprochement*. The way seems now clear for a strong united patriotic party, based not on sectarianism or religious differences, but on a steadfast and manly recognition of all the best interests of India.

For it must be insisted upon that the Muslim position is not grounded upon a blind and implacable hatred of the Hindus, or of any other class of His Majesty's subjects. A foundation of hatred or hostility can never support an edifice of national life, and would be subject to sudden earthquakes when the forces of disorder are let loose. But moral courage, a happy combination of independence and discipline, a directness of aims, and, above all, truth, integrity, and loyalty, are the factors which help forward orderly and sustained progress.

The Muslim leaders have shown these qualities in the past, and will show them again when necessary. Of course, I must be understood to claim no monopoly for them in these matters to the exclusion of other Indians, but I am focussing my attention at the present moment to the community whose fortunes we are interested in to-day. The noble monument of the genius of Sir Syed Ahmed is seen in the living college at Aligarh to-day, and Mr. Badruddin Tyabji has left an inspiring example in his efforts for women's education and emancipation, and in the sturdy

good sense and independence with which he always approached any questions which he handled. It would not, perhaps, be becoming to attempt an appreciation of living leaders; but we are happy in possessing not a few —authors, jurists, lawyers, poets, professors, religious dignitaries, and land-holders — of whom any community may well be proud.

The future of the Muslims rests entirely in their own hands. They number 62½ millions in India, against a total of 250 millions in the world, as estimated by a recent authority. It is true that they are a minority among the 294 millions of the people of India; but they are increasing faster than the Hindus, and if they have any consciousness of moral worth, their influence is, or might be, greater than can be measured by mere numbers. Except in Kashmir and Eastern Bengal, where they form the rural cultivators, and the poorer mass of the people, their centres of population are usually in the towns, and their occupations are usually those above what are called the *Razáil pesha*. Their skilled artisans are famous and have been famous for ages. In the learned professions they occupy a respectable position, though they ought to be better represented than they are. In administrative positions in which manliness, open-air work, and knowledge of men are the chief requirements, they excel. Their literature is both rich and vigorous, and the tinge of melancholy which seems to have rendered turbid its lucid stream will disappear with the advent of larger hopes and fresh streams of thought. It is less sectarian perhaps than the literature of any other people in India. Was it not Malik Muhammed of Jáyas (*circa* 1540) who wrote the Padmávat in excellent Eastern Hindi and prepared the way for that deservedly popular Hindu classic, the Ramayan of Tulsi Das?

What they chiefly require is organisation. Such splendid material should not be wasted for lack of co-operative effort. The different Anjumans which they already possess are excellent institutions, but the Muslims require a healthy organisation of their Church on a purely religious, though broad and non-sectarian, basis. Their social system requires organisation on progressive lines, with more of the valuable benefits of women's co-operation. I have an idea that the women in Turkey, Syria, Egypt, and Algeria (especially the last) are far more advanced than the Muslim women in India, and I am told by a Persian friend—a great admirer of Qurrat-ul-Ain—that the women of his nation are the most advanced of any in Islam. Then, again, our charities and *wakfs* require a thorough examination and complete reorganisation, so that our modern ideas may be brought to bear, as far as is consistent with the donors' wishes, on their administration. We should make these benefactions subserve national progress instead of chartered indolence. Could not Mr. Ameer Ali give us a detailed and reasoned exposition of the subject, dealing not only with abstract generalities, but with concrete and specific instances?

Above all we want a careful and thorough review of our educational position, not only as it touches the men but also as it affects the women. The late Syed Mahmud's book on the subject contains excellent material, though it requires to be digested, brought up to date, and enlarged in scope. The review by itself would be useless if it leads to no practical results. In higher education the results achieved by the Aligarh College are striking: the proportion of Muslims in the United Provinces under collegiate education is a good deal higher as compared with the Muslim population of the province than the proportion of Hindus receiving higher education to the total Hindu population in the province. This fact I mention not for self-congratulation, but in order to draw attention to the other side of the picture in regard to primary and secondary education, and particularly in regard to the education of girls. A system in which the primary and secondary education is not put on a sound and popular basis is liable to become top-heavy. In the Punjab, the Anjuman-i-Himayat-i-Islam has done very good work in the direction of primary and secondary education, and has alway kept in touch with the masses of the people. Their example is to be commended to the Muslim community of the whole of India.

Self-help is a principle which cannot be too much emphasised and urged upon the attention of the Indian Muslims. If they rely upon themselves, they are more likely to obtain the encouragement and practical assistance of the Government than if they constantly harped on abstract principles, or built futile hopes on the treacherous sands of preferential treatment. I have no hesitation in saying that such treatment would be demoralising to themselves, and quite out of the question as the sole crutch to rely upon in this twentieth century. Frank, sturdy, and true was the advice given by the Governor of

Madras (Sir Arthur Lawley) the other day, to a deputation that waited upon him :—

"You tell me," he said, "that a change has come over the spirit of your dreams, that there is a change in your aims and aspirations, that you put before yourselves the goal of national progress. You ask my aid in helping you to attain that goal. I am afraid the days of magic are over. Even a Governor does not possess any mystical power whereby he can expedite to any appreciable degree the advance of national progress; but when you rally your forces to the campaign against prejudice and ignorance, when you make Progress your battle-cry, then, indeed, I am ready to enter into an alliance with you, defensive and offensive."

If I were asked to make a banner for this peaceful campaign of progress, I should inscribe on it the following mottoes: Staunch loyalty to our Sovereign; Patriotism for our country; Friendliness to all our neighbours; and, the sum and substance of them all, Absolute truth to ourselves.*

Note about the Slides shown.

Portraits of celebrities, including Their Highnesses the Nizam, the Aga Khan, the late Begam of Bhopal, Miss Fyzee, the late Justice Badruddin Tyabji, the late Sir Syed Ahmed Khan, Maulána Háli, the poet, and the Emperor Akbar, from a portrait in Valentyn's "Lives of the Great Moghals" (in Dutch), Amsterdam, 1726.

Buildings in Fatehpur Sikri, Sikandra, Delhi, and Agra, to illustrate Moghal and earlier Mohammedan architecture and decorative arts.

Jahangir's zodiacal coinage, to illustrate the legends that gathered round Nur Jahan.

Badshahi Sarai, in Nur Mahal Town, District Jalandhar, built by order of the famous Moghal Queen—to illustrate the manners of the period.

Mausolea of Hyder Ali and Tippu Sultan, and Jami Masjid built by Tippu—to illustrate late Mohammedan architecture in the South.

Bijapur Jami Masjid—to illustrate the grand and original style of architecture, showing Byzantine influences, developed in the South under the dynasty of Yusuf Adil Shah, who was a son of the great Murad or Amurath, Sultan of Constantinople.

The great Bijapur gun, known as Malik-i-Maidan—to illustrate the design and finish which the Mohammedans of the sixteenth century were able to carry out in the art of casting metals. Diameter at breech, 4 ft. 10 in. Col. Meadows Taylor, in 1866, described it as the largest piece of ordnance in the world. Cast by a Turk, Muhammad bin Hasan Rumi, in 1548.

Mosque at Champanir, panel of Arabesque in ceiling—illustrating early Mohammedan art in the old capital of Gujerat.

Ahmedabad architecture, including a window of palm tracery from the Bhadr—illustrating the limits of the natural and the conventional in decorative design. *Cf.* Mendelslo's description (1662) of two rows of palm trees and tamarinds in this very place.

* Mr. Yusuf-Ali has reprinted his paper and the discussion on it as a pamphlet, which will be published by Messrs. P. S. King and Son, 2, Great Smith Street, Westminster.

DISCUSSION.

The Chairman thought the audience had listened with pleasure and interest to the eloquent and instructive address which Mr. Yusuf-Ali had given. He hoped the author would not think it a mean compliment if he said that he had been much struck with the extreme facility and eloquence he displayed in a language which was not his own. If it was borne in mind how few Englishmen there were who had a thorough command of any foreign language, he thought it would be recognised that it was no mean achievement for an Indian to speak and write English as Mr. Yusuf-Ali did. Although the author had not gone any too far into the past history of the Mohammedans, he regretted that the paper was not extended in order that those present might have heard something further about the present and the future. That was the criticism he desired to make—that, animated as everybody was by the modern spirit of hurry, progress, and looking ahead, the present and the future of Mohammedanism in India in a treatise of greater extent would have appealed to them immensely. He thought in dwelling longer on the past than on the present and the future, the author was displaying a very common characteristic of his co-religionists. He would not say that it was a failing, but there was no doubt that the Muslim of India was too fond of looking back to the past. He needed to look more ahead, a fact which he thought the author fully recognised; but he (the Chairman) wished for the sake of those who read the paper afterwards that that point had been more emphasised in the paper. Next, he thought that anyone who read the paper in the future would carry away an undue impression of the ability and the intellectual powers of Mohammedans as a whole in India. No one was more ready to admit than he was the existence of brilliant exceptions in the persons of able Mohammedans in all classes of life, but it would be a wrong impression if anyone thought that the proportion of Mohammedans who were progressive, intellectual, and distinguished was a large one compared with the proportion of other communities. That was fully admitted by the leaders of Mohammedan reform in India. He remembered that Mr. Justice Tyabji, who presided at the Educational Conference in Bombay in 1903, made a very brilliant, candid and courageous address laying great emphasis on that point. He said that "in every department of life, whether it be in the public service or in the liberal professions, the numbers of Mohammedans who

were distinguished civil servants, doctors, engineers, or lawyers, was a mere handful compared to the numbers of those of other communities." He went on to say that the Government had been impartial and fair, and that the backwardness of Mohammedans, which he so fully admitted, was due to their religious and literary prejudices, and to the absence of female education. The author had mentioned so many interesting points connected with the capable Mohammedan ladies, of whom he was most rightly and justly proud, that he thought the audience would go away with the impression that the successors of the Begams, of whom he had told so many stories, the Mohammedan ladies of the present day in India, were a great deal more cultured and capable than they really were. There was a brilliant exception to which the author referred in the person of H.H. the Begam of Bhopal; but he did not think there were many poets, writers, or critics of Holy Writ among Mohammedan ladies who could be at all considered as belonging to the first rank. At the Conference to which he had referred, H.H. the Aga Khan made some remarks, which were also characterised by frankness and courage, and which were of so much importance in view of what had for some time past been the attitude of Mohammedans in India that he had looked them up and made a note of them. His Highness said:—"Providence has given us a Government that guarantees justice, intellectual and religious liberty, personal freedom—a Government that gives a clear field and no favour, that constantly by its own acts reminds us that fitness is the only test, and that for the fit there are no obstacles." That was the attitude of the men of light and leading among Mohammedans in India, and that was the attitude of the author of the paper. Unlike the great majority of his co-religionists, Mr. Yusuf-Ali made no complaint that the Government had been partial, and he had not asked for preferential treatment. Indeed, one of the sentences in the paper which pleased him most was the allusion to the "treacherous sands of preferential treatment." One of the most encouraging things at the present time was that the leading Mohammedans, under the guidance of enlightened and brilliant men of strong character, like the two whose words he had just quoted, were giving up the idea that preferential treatment in the public service would prove their salvation, or be of advantage to them. It was perfectly obvious that a few more billets in the Government service could not possibly be of any appreciable advantage to so vast a community as 62 million people, but yet the humbler Mohammedans pathetically pinned their faith on that hope. It was a comfort that that idea was slowly being given up, and making way for more sensible views of the situation, and to a conviction that in self-help and self-reliance lay the hope for Mohammedanism in the future. During the past five years he had had a good deal to do with Mohammedans. They had come to him with petitions and addresses to which he had to reply, and the burden of them all was "Give us more posts in the Government Service." Those representations were not drafted or instigated by the leading men. With regard to these he desired to say, without any intention of paying a compliment to the author, that the Indian Mohammedans had always had the greatest attraction for him. That attraction was due, not only to their manliness, to their courtly manners, to a sense that they inherited a deep-seated love of learning of an Oriental character, but also to the certainty he entertained of their feelings of loyalty and patriotism. The author concluded his address by saying:—"If I were asked to make a banner for this peaceful campaign of progress, I should inscribe on it the following mottoes:—"Staunch loyalty to our Sovereign; patriotism for our country; friendliness to all our neighbours; and, the sum and substance of them all, absolute truth to ourselves." He thought the Mohammedans of India were true to everyone of those mottoes except the last—they lacked absolute truth to themselves. That could only come from and through themselves; the Government could not help them with regard to that. He sympathised very much with the author when he dwelt on the past of Mohammedanism, because he thought the past was the subject of which Mohammedans had great cause to be proud. There was not only the fact that the Moghals laid the foundations of that British dominion in India of which we are all so proud, that they had laid to a great extent the foundations of that system which England is now carrying on, but also that they had a wonderful history of civilisation and enlightenment to which they could well look back. It was not often remembered by this country that the Mohammedans were the pioneers of civilisation in Europe. All the first great truths regarding mathematics, astronomy, and medicine came from the Arabs who were of the faith of Islam. In the old days the zeal for learning was so great that it was related of one Khalif of Baghdad that he prepared to make war on the Roman Emperor for no other reason than that of compelling him to send to Baghdad a famous mathematician of his court. One could trace back to all that natural and just pride of their ancient learning, power, and enlightenment, the reason for one of the present failings of Mohammedans—they had clung to the old system of education. At the commencement of the British rule they were too prone to neglect Western education, and thus allowed the Hindus to get a start of them in the race. To put the matter quite plainly, in the baldest language, the young Mohammedan was taught the Koran in the school in the old-fashioned way, *i.e.*, he was taught to commit the Koran to memory for several years to the exclusion of his secular education, and, therefore, he was several years behind the young Hindu boy. The same process was going on with the individual as had gone on between the two races. He believed it was a fact, because it had been stated by the great Mohammedan

leaders in India, that Islam was not hostile to Eastern or Western education. The Prophet himself said, "seek knowledge even if it were in China." In the ancient Khaliphates of Baghdad and Spain, to which he had just referred, the works of the Greek and Roman philosophers were read side by side with the Koran, and the faith of Islam was not undermined or impaired in any way. The signs of the times, as the author said, were extremely hopeful. The great work of Sir Syed Ahmed Khan, which could not be over-estimated, was beginning to be appreciated. The Mohammedan educational conference was slowly but surely pursuing its propaganda, and recently a new development had been seen in the deputation to the Viceroy of the Mohammedan leaders of the whole of India. It was a very remarkable demonstration, from which the attitude of Mohammedans towards British rule and towards the question of their own progress was thoroughly patent. He thought it was a most encouraging episode, and one full of hope for the maintenance of a bond of cordiality between the British race and Mohammedans in India, and for the future of Mohammedans themselves. The author had given several charming anecdotes, and he personally would like to emulate his example by giving one also. Mr. Yusuf-Ali had referred at some length to the Wahabis, who might be roughly described as the Puritans and Protestants of Islam. In a sense they represented both those classes, and they were also Unitarians in so far as they were against polytheism. They objected to all gaiety and frivolity, just as Puritans did in old days. One thing they condemned most particularly was smoking; and *apropos* of that he found in Palgrave's book on Arabia a rather amusing anecdote. Palgrave narrated "that one Abd-ul Karim said to him, 'The first of the great sins is giving Divine honours to a creature.' 'Of course,' I replied, 'the enormity of such a thing is beyond all doubt. But if this be the first, there must be a second; but what is it?' 'Drinking the shameful' (the Arabic idiom for smoking tobacco) was the unhesitating answer. 'And murder and adultery and false witness?' I suggested. 'God is merciful and forgiving,' rejoined my friend; that is, these are little sins.'"

Sir WILLIAM LEE-WARNER, K.C.S.I., desired to add the special thanks of the Indian Committee to Mr. Yusuf-Ali for the successful lead he had given in a new departure. In previous years we had heard about Indian arts, finances, commerce, resources, and famines. The Indian Section was now beginning a course upon the people of India, and he hoped that the account of each of the main races would be given by one of that race. The author had not only given an interesting account of his own co-religionists; he had also contrived to show his devotion to his own people without a single word which could possibly offend any one of the other races. He (the speaker) professed himself a disciple of the Swadeshi movement, and the more he thought about the various qualities of the very different races and religions of India the more he felt what a vast resource India possessed in the sum total of their different qualities if only they could be turned to account for the good of their common country. How to utilise these resources of India's manhood for the common good, employing Christians, Hindus, Mohammedans, Parsis, Buddhists and others in the public service, was the great problem, and it could only be solved by knowledge and appreciation of the qualifications of each race. The Mohammedans had turned out great men in the past and there was no reason why they should not do so in the future. Perhaps the Government would be wise in altering some of its methods of selection, perhaps public competition was not the best means of recruitment. But certain it was that we must not let the national resources of India run to waste. We must enlist the best of all races in due proportion in the common work of the public service of that great Empire. He hoped that the paper which had been read and those which were to follow would suggest how this end could be attained.

Mr. AMEER ALI, C.I.E., said the subject of the paper was of especial interest to him, as he had traversed a good deal of the same ground, and it was interesting to notice how the salient features of the history of the Mohammedans of India struck the younger generations of his co-religionists. He thought the reader of the paper had rather lightly touched on the work of the Mohammedans in India. It was usually supposed that the Mohammedans came as conquerors, and long after their settlement introduced political institutions which had been of value to their successors in the work of Government, but the amount of help they had given to the development of civilisation in that country was not recognised. If the history of Mohammedan India was more carefully studied, it would be found that the Mohammedan savants, scholars, poets, and *littérateurs*, who came from the West to India, furthered to the utmost the civilisation of that country, and added to the civilisation of India which had come down from ancient times. He joined in the Chairman's friendly criticism of the paper that it dwelt too much on the past. Personally he had hoped to hear a good deal about the present condition and future prospects of the Mohammedans in India. He thought it was necessary to make a few observations on the question of the *wakf* institutions to which the author had referred. He had devoted some 400 pages of his work on Mohammedan law to the elucidation of the law of *wakfs*. Up to that time he was under the impression that it was English judges only who did not quite appreciate the abstract side of this branch of the Mussulman law, but he was sorry to find the learned reader of the paper felt a similar difficulty. If Mr. Yusuf-Ali would be good enough to explain to him the exact nature of his difficulty he should be very happy to offer such explanation as he could. In 1885 the Central National Mo-

hammedan Association of Calcutta, of which at the time he was secretary, represented to the Government of India that the Mohammedan *wakfs* all over the country, which included provisions for the advancement of education, were being wasted and misapplied. The Government of India moved the Government of Bengal to appoint a Commission for the purpose of investigating the matter. Three members belonging to the progressive section of the Mohammedan community, and three others from a different section, were appointed on the Commission, the Advocate-General of Bengal being the chairman. Unfortunately, the views expressed by the Commission were so divergent that the Government of India felt it difficult to grapple with the matter and dropped it, so that the endowments had gone on as usual, and nothing had been done. It was not the fault of the Mohammedan community; it was the fault, if he might say so with all deference, of the Government, which thought itself so bound to defer to what it considered orthodox views that nothing had been done for the protection of Mohammedan *wakfs*, or for their utilisation for the promotion of education. With all respect, he desired to say that the Mohammedans of India did not seek preferential treatment; they wanted fair and equitable treatment. They felt that within the last few years there had been such a change in the policy of public affairs that they did not get the treatment to which they were entitled.

Mr. THEODORE MORISON (late Principal of the Mohammedan Anglo-Oriental College at Aligarh) said the paper had suggested to him that, in considering Mohammedan history, the author had made it quite clear that Mohammedans had had a tradition of culture which was entirely independent and their own. Even during the time that they had lived in India, although no doubt they had been influenced by their surroundings, that intellectual tradition of culture had been independent. He did not wish to enter upon the very debatable and thorny question of whether the Mohammedans might be considered a nationality of their own in India, but the fact that they had an intellectual tradition constituted a strong argument for what the most enlightened Mohammedans of the present day were asking for, namely, a University of their own. He was aware that was not the opinion of their late University Commission, but it was his own view; in this he was entirely in sympathy with the Mohammedan community. He presumed the author had not referred to that question because it was a debatable one. Mohammedans had in their own language words which would have been extremely useful in the educational broils in which England was now engaged. They had two distinct words for intellectual training and the discipline of character. There was, unfortunately, no word in English to distinguish intellectual instruction from the discipline of character except those rather clumsy and lengthy words. The Mohammedans expressed the distinction by simply using two words: *ta'lim*, to imply intellectual instruction, and *tarbiyat*, to mean discipline of character—the conception being that the training of character was an integral part of education and could not be divorced from it. There was a purely secular education in India, and therefore the training of character took no part in it, because it was felt that, if conduct was influenced, the dangerous ground of religion was entrenched upon. Mohammedans accordingly contended that they should be allowed to carry on the intellectual tradition they had hitherto possessed, and give to their children an education which would not only be educational but include the training of character. One of the present ideals of the Mohammedans was, as he had said, that they should be allowed to have a university of their own, which, of course, was not intended to absorb the whole of the educational institutes of the country at which Mohammedans were at present educated. The Mohammedan leaders, at least, recognised that a university such as they contemplated could only be for a very small number. The great majority of Mohammedans would have to attend local colleges, what might be called "bread and butter" colleges, which students attended simply for the sake of the advantages the training conferred upon them for their work in after life. He knew that view of education had been a good deal sneered at recently in India. To put it frankly, the great majority of people who went to universities, either in England or in Germany, did so because it gave them greater chances and advantages in the struggle for existence; but what the Mohammedan leaders demanded, with, he thought, absolute truth, was that they should have in their community a small number of highly educated men, of scholars, who would increase the reach of Mohammedan thought and diffuse high ideals throughout their community. It was their belief that they might create in one place a sort of intellectual capital for Islam in India, and that was their ideal in wishing for a Mohammedan university.

Sir RAYMOND WEST, K.C.I.E., after joining in the chorus of thanks which had been expressed to the author for his excellent paper, said that matters of Mohammedan history admitted, like the history of other nations and communities, of various views. For instance, the views held in England with regard to English history varied from those entertained on it in France or Germany. He, therefore, thought it was no discourtesy to the paper, the admirable spirit of which he thoroughly recognised, to say it was quite possible to have somewhat different views on some portions of Mohammedan history from those the author had put forth. He invited his hearers to look into the subject for themselves. There was a great deal in Mohammedan history which was worthy of admiration and respect. He was quite certain that the want of respect for Mohammedan feeling, traditions and men, of which there was at least a veiled complaint in the paper, did not really exist; it

was merely a thing conjured up by the over-sensitive imagination of the members of the Mohammedan community. He had had a good deal to do with Mohammedans in his time, both in India and Egypt; and no men in the world with whom he had had to deal had appealed to him more in point of manners and bearing than the Mohammedans with whom he had been brought in contact. They were grave, courteous, modest, and manly in their bearing, and in every way calculated to win the respect and admiration of Englishmen. He believed that, if the English gentlemen who had rendered service to the Government in India were consulted, it would be found that no people stood higher in their estimation, or commanded their respect more than the Mohammedan people; and he trusted that if the author had any lurking suspicion that there was still a want of respect on the part of English people for the traditions of his community, he would put it away from him at once and for ever. The history of the past, however, was of less importance than the position of Mohammedans in the present. He thought the position of Mohammedans in India at present, did present certain difficulties, but they were being fairly faced by the Government; and he had no doubt that a remedy would be found by co-operation between the Government and the most intelligent leaders of the Mohammedan community, such as those who had lately been expressing their views, and also by the influence of such men as the author himself. Mr. Yusuf-Ali had spoken of the necessity of organisation. He thought organisation was even less necessary amongst the Mohammedan community than the formation of a new set of theories and ideals. A great deal of wealth, social and intellectual, might be drawn from their ancient literature, which would be of infinite advantage, as those were the stores from which they ought to draw the principles which were most calculated to benefit them in the future because they were of natural growth. Things which were admittedly exotic seldom took root so thoroughly as those drawn from the stores of one's own history and literature. For instance, Mohammedan law gained no place amongst the Mohammedan community until men of genius contrived to draw out from the then existing sacred literature of the Mohammedans the basis for a structure of Mohammedan law, which had governed the people and been the most potent means of swaying their minds from that period down to the present. He, therefore, thought the author, and other members of the Mohammedan community, should form amongst themselves a set of ideals and theories for the advancement of their people adapted to present needs, but drawn from the riches of their own literature, feeling certain that truth based on those eternal foundations would work itself out to the ultimate benefit of their community.

Dr. Seid Abdul Majid agreed with the author that there was a want of organisation among Mohammedans for placing their grievances and demands before the Government, not that he advocated any proceedings which would detract from the loyalty which Mohammedans observed towards the Government, or be unfriendly to other communities. A centralised Government, such as the Government of India, should study the wants of the people; but, unfortunately, in India the head of the Government was changed every five years, so that just when the Viceroy was beginning to appreciate the wants of the people, and follow out a proper policy, he was recalled. He disagreed with the Chairman's view that Mohammedans were antiquated. The smallness of the number in the Government service was due to the want of interest in the Mohammedans on the part of the Government officials, and not to their want of ability, as had been pointed out in the Address presented to the Viceroy, at Simla, on October 1st. An Address was presented to the Chairman, by the Mohammedans, when he was leaving Madras, and, in reply, his lordship said that the Mohammedans were lacking in pushfulness; but personally he maintained it was the duty of the Government to push them forward. Further, as Mr. Morison had pointed out, Mohammedans required a University which would mould the character of their young men, their ethical needs being entirely different from those of the other races of India. Although the Government, so far, had not supported their appeal, he trusted it would be again considered in the friendliest manner.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Yusuf-Ali for his exceedingly interesting paper.

Mr. J. D. Anderson, late I.C.S., writes:—It seems to me that Mr. Yusuf-Ali's admirable paper provides mattter for thought to all who are interested in India. It brings out, incidentally, how different are our problems from those of other Mohammedan countries. Of the Turkish Empire I will not venture to speak. In a purely Mussulman country the regeneration of the administration is in the hands of the leaders of the people, and European example and advice is probably not of much use. In Tunisia and Algeria the problem is chiefly economical. These countries are being overrun with hundreds of thousands of Christian immigrants from Sicily, Malta, and the Balearic Isles, in search of land to cultivate and of manual labour. The Mohammedans of French Africa are pressing their Government to protect them against the industrial competition of men who are not only aliens but not even French subjects. In Egypt, again, is a different problem. I suppose such men as Mustapha Kamel Pasha, and such newspapers as *El Lewa*, do not aim at making Cairo another such place as Stamboul. I suppose they desire an independent but Europeanised Egypt. In India, as Mr. Yusuf-Ali shows, the problem is

quite different again. There the Mussalmans are not only in a minority, but, in many provinces, are very scattered. There was a time when it seemed as if they were content to dwell as foreigners in India, since they could not have their old position of undisputed rulers of the country; but, as the paper shows, Islam is waking up to the fact that it can claim, if not the old monopoly of rule, yet the share in the administration which is due, not merely to its numbers, but to the energy, the culture, the independence and the honest purpose of enlightened Mussulmans. Now, one of the peculiarities (as has often been noticed) of Hinduism is that, though it is an exclusive religion and makes no direct converts, it is curiously tolerant. The propagandist religions "of the Book" have always had some difficulty in being tolerant, in "rendering to Cæsar the things that are Cæsar's." It was largely Indian dominion that taught Englishmen the lesson that administration in a country where there are many religions must necessarily be (in the modern phrase) "undenominational," and that the government of such a country must be purely secular. If the Mohammedans of India can learn this lesson, they have a great future before them, and especially those who, like the author, possess a high official position The Mussulman in India has to assert his rights as a British subject, has to show, as he can easily show, that to be a Mohammedan by creed is not, as it has sometimes been, a disadvantage but an advantage. History has shown us that Mussulmans can be as tolerant as Akbar himself, as tolerant as the best Anglo-Indian administrators have always been. They will have to assert themselves in secular matters, and hold their own with their Hindu fellow-citizens. But they will have to do this in a spirit of courtesy and tolerance, and not of aggressive superiority or exclusiveness. They must demand a fair field for their energies, commercial, social and political, and must show that the races who once ruled India can hold their own in the modern struggle for life. To do this, they must hold to and assert the doctrine that administration in a mixed country like India must be purely secular, and that religious tests of all sorts must be excluded from public business. They must no longer stand aloof from politics and government, and must claim to be consulted, not as Mussulmans, but as natives of India, whose culture, intelligence, and sincerity of purpose give them a peculiar claim to be consulted. And if all this is true of the Indian Mussulmans, it is equally true of the Indian Christians, many of whom are in a worse state than any of the followers of Islam. They have to show that it is no more a disadvantage, in the social and political sphere, to be a Christian than to be a Hindu or a Parsi, and to show this, not by asserting the superiority of Christians as such, but by proving that the profession of Christianity is not incompatible with civic virtues, business habits and political wisdom. I think all this is more or less implied in the admirable and suggestive paper, the optimistic spirit of which renders it delightful reading to all who believe that the present agitations in India will result in a better understanding between all classes of the King-Emperor's loyal subjects in a country where loyalty is traditional.

Mr. YUSUF-ALI writes:—

As there was no time at the meeting to reply to the points raised in the discussion, I submit the following remarks for insertion in the *Journal*:—

I am under a deep obligation to the distinguished speakers who have joined in the discussion, and to the friendly audience which has given so kind a reception to the subject of the paper. My object was to bring forward a few facts about Indian Mohammedans in as interesting a manner as possible, and to avoid all controversial topics. Had I been speaking to an audience consisting chiefly of Indian Muslims, I should no doubt have felt it my duty to adopt a different mode of treatment. I should then have assumed much of the past, and insisted more on the present and the future of the internal affairs of the people. But in introducing the subject to a London audience, many of whom are probably unfamiliar with it, it seemed to me best to lay before them a few of the undoubted facts of history, facts which continue to influence and shape our ideas at the present day, and will have a great deal to do with the unfolding of our future. It is on the same principle that when we make a new acquaintance, we want to know all that he has done in the realm of action or thought, for that is the surest key to his character, and will enable us to calculate what he is likely to do in a given set of circumstances. At the same time, I am at one with the noble Chairman in his advice to the Indian Mohammedans to look ahead rather than rest on their oars, and I welcome his words, and those of Mr. Ameer Ali as likely to carry much weight and authority with the Indian Muslims.

To Sir William Lee-Warner I owe a debt of gratitude in many ways—not the least for the interesting announcement which he has made about the new departure initiated by the Indian Section of the Society of Arts, over which he so worthily presides. A most encouraging sign of the times is the interest now taken in Indian affairs in the capital of the British Empire. It is possible to hear more papers by the highest authorities on Indian topics in London during the season, than even in Calcutta or Bombay.

On the subject of *wakfs*, the limitation of space and time have not permitted more than the briefest allusion in the paper. I had hoped for a more extended review of that difficult question from Mr. Ameer Ali, who can speak with acknowledged authority. He has not only written about it and taken the action which he alluded to in connection with the Central Mohammedan Association of Calcutta. His long judicial experience, and his share in the practical administration of the Mohsin Fund, would enable him to handle the subject with a

mastery of detail which must necessarily be wanting in mere abstract discussions. What I meant to suggest in the paper was that specific instances of Muslim *wakfs* in India should be taken, their history carefully traced, their original conditions examined, their present administration inquired into, and the influence of legal decisions favourably or adversely to the claims of individuals and communities impartially estimated. Each *wakf* should be treated on its own merits and examined in the minutest detail, and the conclusions should be based, not upon opinions, but upon hard, solid facts, which can be verified by the opponents of any measures which the collective sense of the community proposes after such examination. It seems to me futile to expect unanimity in the community on such a subject, but the treatment of the subject on the lines proposed would be able to carry conviction to all public-spirited minds, and when they speak with one voice, I have not the slightest doubt that the Government would be only too pleased to undertake legislation in a practical spirit.

We must recognise that there are three distinct sides to the question of *wakf*. First, there is the juristic question of the interpretation of the authorities, which are by no means unanimous. Recent rulings of the British courts are in conflict with the carefully reasoned opinions of men like Mr. Ameer Ali, whose views must command the highest respect, on the question of the validity of family settlements. On this side of the question there is a voluminous body of literature, which is reinforced by the demands of those whose chief idea is the conservation of ancient families. This brings me to the second side of the question—that which touches the interests of individuals and families. In many cases these interests are inextricably mixed up with bequests for "pious uses" properly so called, religious purposes, charitable purposes, and purposes of public utility such as educational institutions. To separate and distinguish these different objects is certainly most difficult and not always possible; and yet the task must be attempted if we are to save the most beneficent *wakfs* from the deluge which threatens to swallow up all because certain incidents have been attached to some, which the courts as at present constituted, hold to be inadmissible. Again the definition of "pious uses," "religion" as opposed to superstition, and "charity," as opposed to the nurture of pampered and glittering indolence, vary with the evolution of ideas in the public mind. It is necessary in every individual *wakf* to see what is directly of public benefit and what in the first instance only serves private ends. Save both if you can; but if not, at least save the public benefactions. The third and most important side of the question of *wakf* relates to those which deal with public purposes only. It will be found that many of these have been diverted to private uses, in other words misappropriated—or else applied to purposes other than those originally intended. In each individual case, as men of progress, we have to apply our best ideas to the solution of the difficulties; as practical men, we have to hold the balance even between the donors' wishes, private or vested interests, and public purposes pure and simple. In many cases it will be found that where public and private interests are mixed up, the private interests have been carefully watched by those whom they concerned, while the public interests have all lapsed through lack of organisation, and for want of a strong and healthy public opinion. We ought to create such an opinion, organise it, and make it audible. When a survey in detail, such as I am advocating, is carried out, we shall be able to see exactly our position with regard to *wakfs*, historically and prospectively, and there should be no difficulty in getting reasonable legislation passed in the public interests.

It is in inquiries and questions such as these that organisation is of the utmost value, but I agree with Sir Raymond West that, unless the organisation is vivified by ideals—strong, true, and honest—it would not help, nor give us those moral impulses which would carry us over difficulties. When I pleaded for greater respect for the history and traditions of the Indian Moslems, it was in no spirit of complaint, but rather in the hope and belief that more knowledge of each other among the different races who have to deal with India might lead to a better understanding and facilitate the work of Government on the one side, and peace and progress on the other. On that head, the assurances of Sir Raymond West are most valuable, and, considering his distinguished career in Egypt and India, have the greatest significance.

I am glad my friend Mr. Theodore Morison was able to bring forward the question of university education. As a controversial topic I could not discuss it, which was, perhaps, as well, as it brought out the interesting and original points which Mr. Morison has put before the meeting.

Mr. Abdul Majid has tried to defend the Mohammedans from the charge of being antiquated. I am not sure that it is such a heinous charge after all. In some quarters it may even be gloried in, if the only alternative was the maxim: "Get in politely if you can, but if not, get in anyhow."

There is only one point of view not represented in the discussion. I wish it had been possible for an enlightened Hindu or Parsi gentleman to have told us how this presentation of the Muslim case strikes his community. But perhaps that may yet come when the hopes and aspirations of those communities are brought forward before this Society.

GOOSEBERRY MILDEW.

The Board of Agriculture and Fisheries have received information that the American gooseberry mildew (*Spaerotheca mors-uvae*) has been discovered in more than one place in England, and as there is

reason to believe that the disease, in at least one case, is of some years standing, they think it desirable to warn all fruit-growers, nurserymen, gardeners, and other growers of gooseberries of the dangers involved. The disease, which is termed American owing to the extensive damage it has done in America, is of a very serious character, and has rendered the culture of gooseberries unprofitable and practically impossible wherever it has appeared.

The mildew generally becomes visible during the last half of May or the first half of June, when it appears in the form of "glistening frost-like spots" on the fruit on the lower part of the bush where there is usually dense shade. It then spreads to the leaves and tender shoots. In its earlier stages it has a cobwebby appearance, which soon becomes white and powdery from the development of the light conidial spores. Later in the season the leaves and other parts affected turn a rusty brown. The fungus prevents the berry from growing, and the fruit becomes worthless. All during the summer, therefore, the disease can easily be detected and the bushes can be dealt with according to the extent of the disease. But during the winter the disease remains dormant and will not spread from plant to plant. During this period, however, it can be conveyed from one district to another in bushes and stocks. It is clear that enormous and irreparable mischief may be done in this way, and it is the duty of all nurserymen to take precautions not only for their own sake but for the sake of the locality in which they live.

The Board of Agriculture and Fisheries, therefore, urge all nurserymen and market gardeners who intend to buy bushes or stocks of *Ribes aureum*, whether from abroad or from Ireland, or even from other growers in Great Britain, to observe the following precautions :—

(1) Only to purchase from those growers or dealers who are prepared to offer a guarantee that the plants they are selling are of their own growing, and that no case of American gooseberry mildew has ever appeared in their gardens, or in the immediate neighbourhood, and that the said plants have not been near any gooseberry plants recently brought on to the seller s premises.

(2) To plant such gooseberry bushes or stocks as they may buy or acquire from other premises than their own, in a special part of their nursery or garden at some distance from other gooseberry bushes.

(3) To destroy all plants found to be affected with the mildew, and to spray with Bordeaux mixture all others suspected of being infested with the object of destroying any external mycelium or adhering spores that may be present. This should be carried out during the period when the disease is dormant.

(4) To keep a careful watch on all gooseberry plants in the forthcoming spring for any signs of mildew, and to report any appearance suggestive of the disease to the Secretary of the Board of Agriculture and Fisheries—4, Whitehall-place, London, S.W.—immediately it is detected.

(5) To assist the Board in discovering any unreported cases of the infestation during the past summer.

There is at present no law dealing with the eradication of the pests of fruit trees in this country, but the Board believe that the American gooseberry mildew has not spread very far as yet, and that it depends very largely on the action of the fruit growers, nurserymen and market gardeners whether its further development can be prevented.

THE USES OF COTTON SEED.

At a recent meeting of the Cotton Seed Crushers' Association, at Atalanta, Georgia, some interesting facts were brought out in regard to the uses of cotton seed, both for home and export purposes. One of the speakers, who was in early life a cotton grower, said that he remembered well when cotton seed was burnt to get rid of it, but last year there were 4,500,000 tons of cotton seed bought from the planters in the Southern States of America, and the sum of £15,000,000 paid to them, thus adding practically 25 per cent. to the value in that way of the cotton crop. This has been brought about principally through the cotton-seed oil industry. There are probabilities of still further developments in the use of cotton seed, which will increase the value of the product. Professor J. H. Connell, in speaking of cotton-seed meal as human food, showed some biscuits and cakes made from a combination of cotton-seed meal and wheat flour. They were pronounced as delicate and tasty as any product of the flour barrel by the members of the convention who were given an opportunity to partake of them. Another use of seed is that for fertilisers, in the shape of meal. The use of the raw seed to enrich the land was pronounced a waste when the meal can be used to much better financial advantage. Professor Connell said that within a short time he believed that cotton-seed crushers would be able to announce an actual discovery of 4,500,000 tons of a new product fit for human consumption. He stated that he had used cotton oil as a cooking fat for six months, and that it was equal in all respects for cooking purposes to the best lard. By an invention of comparatively recent times cotton oil is freed from the old impurities which gave it a rank odour. So-called olive oil, which reaches America from Southern Europe, carries a large percentage of cotton-seed oil. Cotton-seed meal is used in making biscuits, pancakes, gingerbread, cakes of all kinds, and for various other purposes. The United States Department of Agriculture says that cotton-seed oil "is worth, for food purposes for animals, about double the value of timothy hay, and cotton-seed meal, for the same purpose, is worth three and a third times as much as corn meal." About £6,000,000 worth of cotton-seed oil is exported, and that is only one-third of the product. Fifteen years ago 500,000 barrels of cotton-seed oil were made, which number was increased to over 3,000,000 barrels for the past season.

HOME INDUSTRIES.

Workmen and Co-operation.—In the year 1883 the co-partnership productive societies established by the workmen themselves, numbered 15, with an aggregate capital of £103,000; to-day they are 124, with a capital of £1,819,000, and a turnover of nearly £3,700,000 per annum, the annual aggregate profit being £190,000. These figures show how great has been the progress of these societies in recent years. The same may be said in somewhat lesser degree of co-partnership and profit-sharing by employees in companies and private firms. The annual report of the Labour Co-partnership Association gives some striking figures in support of this statement. For the year ended June last, five gas companies, the South Metropolitan, the Commercial, the South Suburban, the Newport, and the Chester, allotted £53,250 amongst 7,200 workmen as their share of profits over and above the ordinary standard wages. All told these five companies have divided £369,500 among their workpeople, who now have £368,500 invested in shares, or deposited with the companies. Moreover two of these companies have included their workmen in their directorate, the South Metropolitan Company having three representatives of the men on its board, and the Commercial four.

Cotton Spinning Profits.—1906 was a profitable year for spinners, but not quite so profitable as 1905. Taking 90 companies, with a total capital employed of £5,102,360, the average profit in 1905 was £7,701; in 1906, £6,555, or a profit per centage in 1906 of £17 1s. 4d., as against £19 3s. 6d. in 1905. But whilst the profit earned in 1905 was substantially larger than in 1906, the average dividend paid in 1906 was 9⅜ per cent. against 7 per cent. in 1905, the explanation being the large number of adverse balances in the earlier year. Notwithstanding the higher dividends paid in 1906, the credit balances and reserves now stand at £642,306 as against £400,004 last year. The profits earned are much larger than the dividends distributed would suggest. The profits of 1905 were 19 per cent.; in 1906, taking the 90 companies named, they work out to 17 per cent. Moreover, this profit was made by companies which are users of the oldest type of plant, and issue full detailed accounts of the capital employed. But there are many other companies which do not announce the profits earned. These companies paid out dividends and bonuses averaging 13 per cent. against 9⅝ per cent. paid by them in 1905. The present margin between raw cotton and the produce of yarn, is more satisfactory than it was at the beginning of 1906, and the profits and dividends expected in the immediate future promise to create a fresh record in the history of cotton spinning. During 1906 a large number of new companies were formed for the erection of up-to-date mills for the consumption of American and Egyptian cotton, and the producing capacity of these mills is estimated at not less than 2,000,000 spindles. But it takes more than a year to build and equip a mill, so that the markets have not as yet felt the full force of the increase of plant. The present prospects of the cotton crop of the world for 1907 are good, and the indications point to another good year. But the outlook is not altogether without clouds. Should the present activity in trade continue it may be expected that there will be an agitation for increased wages; apprehension is being expressed as to the effect of the large number of new mills that have been erected; and there is even scarcity of labour to work the existing machinery. It may be noted that, taking the last 23 years, aggregate profits were made in 17 years of £3,972,870, and losses in six years of £266,766, leaving a net profit earned of £3,706,104, or an average of a little over 7 per cent. Last year's average dividend of 9⅜ was the highest, the next highest being 7 1-16 in 1901.

Railway Companies and the Public.—The Report of the Board of Trade upon the cases arising in 1904-5, in which it has acted as mediator between railway companies and their customers, tends to show that the right of appeal to the Board of Trade, given to the public by the Act of 1888, is valuable. This Act authorises and requires the Board to investigate complaints, and to call upon the railway companies concerned for an explanation, but does not give it the power to enforce its decision. If the Board cannot effect an amicable settlement, all it can do is to report to Parliament, "with such observations as it shall think fit." The practical result of that Report is not immediate, but it may influence after-legislation. During the two years covered by the Report the Board took action upon 146 complaints, most of them touching high or disproportionate rates, damage sustained, or alterations in the companies' regulations. In many cases official attempts at reconciliation were unnecessary, as the companies, upon being made acquainted with the grievances, satisfied the complaints. The Report says that in most years nearly half the cases inquired into are settled "more or less to the satisfaction of the complainants", who, it may be presumed, owe their redress to the Board. In the remaining cases either no arrangement can be arrived at, or arbitration decides that there is no appreciable grievance.

The Cycle and Motor Industry.—The past year has been a remarkable one in the history of these industries. The motor industry has enjoyed unprecedented prosperity. One company has made a profit in the year of £213,000, and after paying a 20 per cent. dividend, carried £120,000 to reserve, and £48,000 forward. Another made a profit of £106,000, and a third of £75,000. The sales of the leading companies at the shows were a record, and two of the companies have orders on hand that will keep them engaged throughout the present year. One firm has intimated that it cannot guarantee delivery before February, 1908, and a very big order for motor omnibuses has been going a-begging owing

to plethora of work already contracted for. As a result, there is no diminution in the cost of these vehicles, and it is impossible to foresee when the motor-manufacturing companies will have the incentive supplied by diminishing orders to produce vehicles at a price more in conformity with cost. On the other hand, there has been great reduction in the cost of cycles, tyres, and tubes, and the introdnction of the long credit system, both changes intended, of course, to attract orders. Although the cycle trade is not in the exceptional position of the motor industry, it has had a very prosperous year, and its turnover has exceeded even that of the abnormal year, 1895. The total output of cycles has reached nearly to a million of machines, and the exports represent in cycles and accessories about half a million sterling, the exports of motors, and motor parts for the year being nearly three quarters of a million. It is to be noted, however, that there is still a very large import of motor parts. The tube branch of the trade has not shared in the prosperity of the cycle trade. Over-production, and excessive rate cutting have led to heavy losses the largest of the tube companies having found it necessary to go into liquidation. The tyre branch has been more successful, and it is anticipated that the present year will be a period of great activity. Some of the cycle companies propose still further to reduce prices, more especially the cost of the higher grades, hoping to find ample compensation in increased output. It is to be regretted that the abnormal demand for motor-cars of different kinds must postpone indefinitely the reduction in cost which is imperative before there can be any general use of the motor outside omnibuses and tram-cars.

Poultry Farming.—There will be general agreement with Mr. Austen Chamberlain in his regret that cottagers do not more generally keep poultry, and so attract to themselves much of the £3,000,000 that now goes to the foreigner every year for eggs. Not only profit but pleasure can be derived from keeping fowls, and most villagers have room enough to keep them if they wish to do so. The successful rearing and keeping of poultry requires intelligence and unremitting attention, but nothing beyond the capacity of the ordinary villager.

The Coal Industry.—1906 was a very favourable year for coal owners. Unlike the iron and steel industries, which owe the exceptional prosperity of the year to the export demand, the home consumption of coal has greatly increased. The statistics for the full year are not as yet complete, but for the eleven months ended November 30th the exports of coal, coke, and patent fuel, were eight millions in excess of the corresponding period of 1905, and probably the gain for the year will be close upon nine millions. And so with the consumption of coal in the United Kingdom. In 1905 it was 169,017,000 tons, in 1906 it was some millions larger. The total output of coal in the earlier year was 236,129,000 tons, in 1906 it was between five and six millions in excess of those figures. In South Wales the best Cardiff steam coal has gone up to 17s. per ton, and best Monmouthshire coal to 15s. 6d. In Newcastle best Northumbrian steam coal has advanced to 12s. 6d. per ton, and Durham unscreened to 11s. per ton, whilst in Scotland prices have increased in similar degree, and the collieries are finding it difficult to keep pace with the demand. The outlook for the new year is exceptionally promising from the coal masters' point of view, for the demand continues to grow and the threatened labour troubles have disappeared. It is true that in the North of England the miners have given notice to terminate the Conciliation Board, but there is no difficulty as yet as to wages. In the Midlands the Conciliation Board for the federated area has been renewed for three years as from January 1, subject to the right to terminate the agreement by a six months' notice "in the event of any compulsory limitation of the hours of underground labour." The Scotch Conciliation Board has also brought about a settlement between the Scotch coal-masters and miners due to some concessions on the part of the coalowners which give the men an immediate advance equivalent to about 3d. per day. These arrangements point to an improved and improving condition of the trade just as the successful refusal of the shipbuilders in Scotland to concede the demands of the men on strike, and the unconditional surrender of the strikers, indicated the opposite in the shipbuilding industry.

CORRESPONDENCE.

FRUIT GROWING AND BIRD PROTECTION.

I read with much interest Mr. Hooper's paper on "Fruit Growing and Bird Protection," but it seemed to me that, both in that and the subsequent discussion, one of the most serious injuries caused by birds was too lightly dealt with. I refer to the ruin caused to pears generally, and to some of the choicer apples, by the growing habit of some of the tits, notably the tomtit, of pecking a hole in the fruit long before it is ripe, close to the stalk. This lets in water, flies, wasps, &c., and every fruit so pecked is irretrievably ruined. I have seen a fine crop of the pear *Doyenné du Comice* destroyed, with the exception of perhaps half-a-dozen, in this manner, and every year the habit seems to increase, so that it is becoming most difficult to save any choice pears at all. The mischief is done here long before sunflowers are ripe for seed, so that they would be no protection. What seems to be needed is some artificial protection, such as a small wire cap, to hinder the birds from getting near the stalk of the fruit, and I have already one in hand for trial next summer. If this fails, the only resource is to destroy the tits, or get no pears.

LOWTHER BRIDGER.

Old Manor-house, Walton-on-Thames,
29th December, 1906.

OBJECTIONS TO THE COMPULSORY INTRODUCTION OF THE METRIC SYSTEM.

I have read with interest Sir C. M. Watson's paper against the introduction of the metrical system into England, as it is always instructive to hear the arguments of one's opponents. I would not trouble you with this letter, however, were it not that I have seen no correction of the mis-statement made in including Spain in the countries using principally native measures. This is not so. The metrical system is the only recognised basis of weights and measures, and it is used universally except in a few out-of-the-way country places.

As regards its adoption, I do not think anyone who has not lived and worked in a country using the metrical system can be qualified to express an opinion on such an important matter. All the English engineers I have known who have worked for any length of time in Spain recognise its advantages, and would not, I think, go back to our complicated English weights and measures for choice. It requires an equal knowledge of both systems to say which is the better, and the majority of the opponents of the metrical system only seem to know it in theory.

It is also incorrect to state that the division of the circle into 400 grades has never been adopted. Hundreds of engineers use tacheometers so divided, and, moreover, the greater part of these are made in England. For rapid reading, as with tacheometrical surveying, the centesimal division is much more convenient, and has the additional advantage of lending itself to calculation with the slide rule. For astronomical purposes I have also used it, and have found no difficulty when using the suitable logarithmic tables and astronomical data.

My only object in writing has been to draw attention to the above facts which should not be allowed to pass uncorrected. As to the adoption of the metrical sytem, I am fully convinced it will ultimately force itself upon England without compulsory legislation, but this desirable attainment might be expedited if the State would adopt it for official purposes (such as contracts, &c.), and include it as obligatory in all school programmes. In a couple of generations the old methods would disappear of themselves.

GUSTAVE GILLMAN.

OBITUARY.

LADY BURDETT-COUTTS. — Angela Georgina Baroness Burdett-Coutts who died on Sunday morning, 30th ult., was one of the oldest members of the Society of Arts, having been elected in 1848. She was proposed for election by Michael Faraday. Miss Burdett was the youngest daughter of Sir Francis Burdett by the daughter of Thomas Coutts, the founder of the famous bank which bears his name. Coutt's widow (then Duchess of St. Albans), who died in 1837, left the great wealth she had received from her husband to his granddaughter, who was then only three and twenty years of age. From that time to the present she was a prominent figure in the philanthropic world, and one of the first to adopt a systematic and catholic system in the distribution of her charities. The record of her good deeds is a long and brilliant one, but as it is fully set out in the obituaries of the public press it is not necessary to repeat it here, suffice it to say that she founded and endowed numerous public institutions for religious, benevolent, and philanthropic purposes, including bishoprics in Adelaide, British Columbia, and Cape Town, the church and schools of St. Stephen's, Westminster, and St. Stephen's Church, Carlisle, model lodging-houses in Bethnal Green, Columbia Market, and Westminster Technical Institute. In May, 1871, Queen Victoria conferred a peerage upon Miss Burdett-Coutts, and in July, 1872, she received the freedom of the City of London, the only lady who had ever received that distinction.

Lady Burdett-Coutts took much interest in the department of women's work at the Chicago Exhibition, and H.R.H. the late Duchess of Teck writing to the committee said: "Great as have been the intrinsic benefits that the Baroness has conferred on others, the most signal of all has been the power of example—an incalculable quantity which no record of events can measure."

NOTES ON BOOKS.

THE COMPLETE PHOTOGRAPHER.—By R. Child Bayley. Methuen: London, W.C.

The number of books of instruction in photography is now so great, and the information they contain so complete, that there would appear small need for an addition to the list. Yet this handsome volume may fairly be said to justify its existence. The public for which it appears to be intended is a large one, consisting of the very numerous class who without much —or perhaps any—scientific knowledge, practising photography as an agreeable pastime, find themselves pleased with its results and interested in its processes. Such persons will find just what they want in Mr. Child Bayley's pages, full information about the apparatus, materials, and methods they are using, without the need of any recurrence to first principles, or any demand for a knowledge, even an elementary knowledge, of chemistry or physics. Anybody, merely aiming at results, and not seeking to know how those results are acquired, will find just what he wants, and probably all that he wants. First, the apparatus is described, the camera, in its various forms, and the lens. A sufficient explanation is given

of optical principles, and the various classes of lenses are described with sufficient detail to guide the amateur in his selection. Chapters follow on "Plates and Films,', "The Dark Room," "Exposure," "Development," "Intensification and Reduction." Next comes a special chapter on "The Hand Camera." Then the various printing methods are described—silver (P.O.P. and bromide), platinum, and carbon. There are chapters on enlarging and slide making, and on colour photography. Landscape photography, architectural photography, and portraiture have each their special chapter; and divers miscellaneous matter are fully treated. There is a final chapter on "Photography and the Printing Press." There are a large number of illustrations, excellent examples of modern work, but not in any way connected with the subject-matter.

Producer Gas. By J. Emerson Dowson and A. T. Larter. Longmans, Green and Co., London. 1906.

This book contains a very full account of the manufacture of Producer Gas, its use in gas-engines, and a history of the growth and progress of the invention. To a large extent it is an account of the work of one of the authors, Mr. Emerson Dowson, whose name has been so closely associated with the use of producer gas for the development of power. As is well known, the crude gas, known by this somewhat awkward name, was first used to any extent by the Brothers Siemens, and it is to Sir William Siemens that the chief application for such gas in the regenerative furnace is due. In 1878 Mr. Dowson endeavoured to improve the manufacture of the gas by purifying and cleaning it, so as to render it available for heating purposes in general factory and domestic work, the object being to provide a gas which would pass freely through pipes and taps without clogging them, the improvement being mainly effected by passing the material through scrubbers, and washing it in the usual way. This treatment of the gas naturally eliminated some of its constituents which were useful for heating purposes, and the gas was in any case much weaker than the ordinary coal gas used for lighting purposes, which was applied in the first instance to the driving of gas-engines. At the same time its much greater cheapness offered many advantages, and Mr. Dowson set himself to manufacture a gas suitable for gas-engine work. His first paper was read in 1881 at the York Meeting of the British Association, where a 3 horse-power Otto engine was shown working with producer gas. In the same year an engine was shown at the Paris Electrical Exhibition. In the following year he read a paper (which received the Society's medal) before the Society of Arts. At that time there is believed to have been no gas-engine working which developed more than about 12 horse-power. For some time the difficulties in the way, and the fact that so long as small power engines were used, the cost of the fuel was not a very important consideration, stood in the way of the application of cheap gas to gas-engines. But as is well known the invention has been developed, both by the improvement of the gas itself and the adaptation of large gas-engines to its use, until there are at the present time many gas-engines of 1,500 and 2,000 horse-power working satisfactorily with producer, or blast furnace, gas; such gas is also used to a large extent for heating purposes.

The treatment of the whole subject appears to be very complete, and though, as above-mentioned, it is of necessity to a large extent a record of the work of a single inventor, this fact would hardly be realised by a reader of the book (could any such student of the subject exist), not previously familiar with Mr. Dowson's contributions to a very important development of the means of generating power for industrial purposes.

GENERAL NOTES.

The Price of Food in Germany.—Some interesting figures are given by Mr. Consul Buckmann as to the price of food in Germany, in his report upon the Trade and Agriculture of Bavaria (Cd. 2682) for 1905-6. In Munich the consumption of beer would seem to be falling rapidly, the consumption *per capita* in 1879 being 110 gallons per annum, and in 1904 only 69 gallons. Over the same period illegitimate births have fallen from 29·3 per cent. to 25 per cent. To what extent, if any, the growth of temperance has affected illegitimacy must be left to speculation. Mr. Buckmann says that there is good authority for stating that the keep of a German workman has increased in cost by 25 per cent. since 1904, meat alone having risen 35 per cent., whilst wages rose 10 per cent. only. That the general cost of living is increasing is proved by the fact that the military administration require now £4 per annum more than formerly for the maintenance of a soldier. The consumption of horseflesh continues to increase. At Bayreuth, for example, with a population of over 30,000, 239 horses were slaughtered in 1905, against 57 horses in 1902, and in Munich 2,893 against 2,592. In 1904, 81,312 horses and 1,177 dogs, and in 1905, 96,534 horses and 1,584 dogs were slaughtered for food in the German Empire. It is estimated, too, that in spite of a rapidly-growing population, cattle are growing fewer, the decrease in Bavaria amounting to 8·5 per cent. for the period from 1900 to 1904. In Germany there was for every 100 inhabitants 35·4 head of cattle in 1897, 33·7 head in 1900, and 32·2 head in 1904. The 20·8 sheep for 100 inhabitants in 1873 has now fallen to 13·1.

Cotton and Rubber in Sierra Leone.—The cultivation of cotton in Sierra Leone makes very slow progress. It is not systematically carried on by the natives. The species cultivated is indigenous, and

the lint obtained from it is not of good quality. In certain parts of the protectorate native cloth is manufactured for local use, and only sufficient cotton is grown to meet the needs of this industry. On the plantation of the British Cotton Growing Association, at Moyamba, says the Governor, in his report (Cd. 2684), 1,030 acres of land were under cultivation during the year, the experimental planting covered an average of 648 acres, and various types of seed were experimented with. The total quantity of cotton exported in 1905 was 31 tons, an increase of 18 tons over that of 1904. The greater part of this cotton was shipped by the Association, and 80 per cent. of it was purchased from the natives. The export of rubber shows large increase, exceeding by nearly 300 per cent. the amount shipped in 1904. Most of the increase was in "root rubber," which means rubber obtained by cutting up a vine at its roots into short lengths and boiling the cut fragments. Some fragments of the roots always remain in the soil, so that no danger exists of the plant becoming exterminated.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

JANUARY 16, 1907.—Adjourned Discussion on Mr. J. W. GORDON'S paper, on "Patent-law Reform." SIR WILLIAM PREECE, K.C.B., F.R.S., will preside.

JANUARY 23.—"The Isthmus of Panama." By PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

JANUARY 30.— "Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 24.—"The Bhils of Western India." By CAPTAIN E. BARNES, Indian Political Department. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 15.—"The Progress of the Uganda Protectorate." By GEORGE WILSON, C.B., Deputy Commissioner Uganda Protectorate. Colonel SIR FREDERICK D. LUGARD, K.C.M.G., C.B., D.S.O., will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

January 28; February 4, 11.

JUVENILE LECTURES.

Wednesday afternoon, January 9, 1907, at 5 o'clock.

"Perils and Adventures Underground." By BENNETT H. BROUGH. (Lecture II.)

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 7...Chemical Industry (London Section), Burlington-house, W., 8 p.m. Mr. Walter F. Reid, "The Sixth International Congress of Applied Chemistry at Rome"

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. Warren Upham, "The San Francisco and Valparaiso Earthquakes and their Causes."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. H. Bradley, "English Place Names."

TUESDAY, JAN. 8...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Mr. W. Duddell, "Signalling to a Distance from Primitive Man to Radiotelegraphy." (Lecture VI.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Auctioneers, 34, Russell-square, W.C., 7½ p.m. Mr. S. Jackson, "The Metric System."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Francis Fox, "The Simplon Tunnel."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Lecture on "The American Gooseberry Mildew."

WEDNESDAY, JAN. 9...SOCIETY OF ARTS, John-street, Adelphi, 5 p.m. (Juvenile Lecture.) Mr. Bennett Brough, "Perils and Adventures Underground." (Lecture II.)

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Ethological, 6½, Suffolk-street, Pall-mall, S.W., 8½ p.m. Dr. Macnamara, "The Effect of Elementary Education on English Character."

Geological, Burlington-house, W., 8 p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. F. Victor Dickens, "The Beginning of Ancient Japanese Literature."

THURSDAY, JAN. 10...Antiquaries, Burlington-house, W., 8½ p.m.

Junior Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Mr. Alfred Powell, "Pottery."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. M. N. Drucquer, "International Aspect of Marriage and Divorce."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. James Swinburne, "New Incandescent Lamps."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, JAN. 11...Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. A. T. Weston, "The Balancing of Internal-Combustion Motors Applied to Marine Propulsion."

Astronomical, Burlington-house, 8 p.m.

Philological, University College, W.C., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Journal of the Society of Arts.

No. 2,825. VOL. LV.

FRIDAY, JANUARY 11, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, JANUARY 15, 3.30 p.m. (Colonial Section.) GEORGE WILSON, C.B., "The Progress of the Uganda Protectorate."

WEDNESDAY, JANUARY 16, 8 p.m. (Ordinary Meeting.) Adjourned Discussion on Mr. J. W. GORDON'S paper on "Patent Law Reform."

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

On Wednesday evening, January 9th, Mr. Bennett H. Brough, delivered the second and last lecture of his course of Juvenile Lectures, on "Perils and Adventures Underground."

The lecturer commenced with a description of those dangers to which the miner was exposed, that had not received attention in the first lecture. Inundations, in which water had closed the only means of escape, had caused some fearful catastrophes, as at Bessèges, France, where the river burst into the mine when 139 men were at work. Similarly, on February 9th last, the flooding of the shaft at South Rose Deep mine, Transvaal, resulted in the death of 53 Kaffirs. In 1862, at the Hartley Colliery, 199 miners perished for want of means of escape, the shaft being blocked to a height of 400 feet from the bottom in consequence of the beam of the pumping engine breaking and falling down the shaft. Since then the law has compelled every mine to have two means of egress. In the Bessèges accident all were killed except five who were rescued after 13 days. A still more remarkable instance of rescue happened in Scotland in 1835, when owing to a fall of ground a miner 66 years of age was entombed and brought out alive after 23 days confinement without a particle of food. Similarly, Hicks, the Cornish miner, was rescued at Bakersfield, California, on December 21st last, after having been entombed for 13 days.

Serious accidents had also been caused by mine fires. One of the most appalling disasters of this kind was at a silver mine at Przibram in Bohemia. The fire in the shaft, the deepest in Europe, resulted in the death of 319 miners, the cause being a smouldering piece of lamp wick carelessly thrown aside which set fire to the shaft timber. The fatal accident at Snaefell lead mine, in the Isle of Man, in 1897, memorable for the heroic conduct of the late Sir Clement Le Neve Foster and Mr. G. J. Williams, H.M. Inspectors of Mines, was due to the effect of poisonous gases in connection with an underground fire. Accidents at quarries were of frequent occurrence, and statistics proved that the workers inside a quarry had a more dangerous occupation than the average collier or metal miner.

The lecturer then passed on to the subject of fire-damp, imagined by many to be the most formidable enemy that the miner had. From time to time there was news of some terrible colliery explosion, such as that at Wingate Grange Colliery on October 14 last, claiming scores of victims at once; but every day fatalities from falls of roof added up to a far higher total. Indeed, statistics showed that, while of every 100 deaths from accidents, 45 were due to falls of ground, 26 to miscellaneous accidents from fires, irruptions of water, explosives and machinery, 11 from surface accidents, and 6 from accidents in shafts; not more than 15 were due to explosions of fire-damp or coal-dust.

Experiments were shown, illustrating the properties of the dangerous gases met with in mines, and the principle of the safety lamp invented by Sir Humphry Davy, in 1816. Various types of safety lamp were shown, the latest being the Davis lamp, constructed to

be lighted electrically only when the lamp was closed, and provided with a lead plug to lock it. The various methods of lighting underground workings previous to the invention of the safety lamp were described, including the flint-mill invented by Spedding in 1775. The use of the safety-lamp in detecting the presence of explosive gases was pointed out, and the appliances used in the perilous duty of endeavouring to save the survivors after a colliery explosion were described. The most efficient apparatus shown was that devised by Mr. Meyer, which did good service at the Courrières colliery. There, on March 10 last, the most appalling catastrophe recorded in mining history occurred and caused the death of 1,101 men. The explosion was thought to have been due to coal-dust without fire-damp, and to have been caused by a blown-out shot. The heroic work done by the Prussian salvage corps, who at once hurried to the spot, had brought the subject of rescue appliances into great prominence. The author concluded by pointing out that the miner's calling, though a dangerous one, was not nearly so dangerous as that of men engaged on large engineering works, on railways and on merchant ships.

In illustration of the lecture, miners' safety lamps were lent by John Davis & Son, Ltd., Derby; the Evertrusty Shamrock rescue apparatus, as used at Courrières, by Wallach Brothers, 57, Gracechurch-street, E.C.; and models and diagrams by the Board of Education.

The CHAIRMAN (Sir Steuart Bayley, K.C.S.I.) proposed a hearty vote of thanks to Mr. Brough for his interesting course of lectures, which was carried unanimously.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ARTIFICIAL FERTILISERS: THEIR NATURE AND FUNCTION.

By A. D. HALL, M.A.,
Director of the Rothamsted Experimental Station, Lawes Agricultural Trust.

Lecture III.—Delivered December 3, 1906.

THE NITROGENOUS MANURES.

With the time at my disposal in these lectures, it would barely be possible to enumerate the properties of the nitrogenous manures, still less to discuss them with any fulness. I shall prefer, therefore, to bring forward certain points in the behaviour of these particular substances, which are not yet the common property of the text-books but which ought to be borne in mind in the application of these manures in practice.

We can begin by dividing the nitrogenous manures into two classes, the quick and the slow acting, in the first of which we have practically only nitrate of soda, sulphate of ammonia, cyanamide, and nitrate of lime. Our acquaintance with the two latter is too limited as yet to enable us to do more than predict that they will fall into line with sulphate of ammonia and nitrate of soda respectively. Nitrate of soda has now been in use in this country for something like seventy years, the Chilian deposits having been first discovered about the time of Darwin's voyage round the world in the *Beagle*. As nitre had long been known to possess great manurial value, the exportation of nitrate of soda to Europe was at once suggested, and in 1830 it appears that a trial shipment was made of 18,700 quintals of about 100 lb. each. By 1838, the date of the first volume of the "Journal of the Royal Agricultural Society," it was being tried experimentally by a good many landlords and farmers in this country. The production grew rapidly, and reached its maximum in 1899 when 1,344,550 tons were consumed; since then the output has declined a little owing to combination between the producers. At the present time the United Kingdom takes about one-twelfth of the total production, Belgium an equal share, France and the United States about one-sixth each, and Germany rather more than one-third of the whole. Opinions differ greatly as to the approaching exhaustion of the Chilian deposits; various estimates set their probable life at from twenty to forty years, but doubtless long before exhaustion sets in, the poorer grounds, now being neglected as containing less than the paying amount of nitrate, will be exploited, provided always that the artificial nitrate of lime does not render the whole industry unprofitable.

As to the origin of the nitrate of soda deposits there are two theories, to understand which some description of their mode of occurrence is necessary. The chief deposit lies in the province of Tarapaca, in Chile, on an elevated plain known as the Pampa of Tamarugal, about 3,000 feet above sea level, stretching for a breadth of some thirty or forty miles from the Corderillas on the eastward to a low range of foothills separating it from the sea

The climate is intensely dry, rain falling only every two or three years and then only in quantities which rapidly evaporate. The special nitrate-bearing deposit or *caliche* occurs a few feet below the surface, and is associated with earthy matters, gypsum, common salt, and sulphates of sodium and potassium. The generally accepted theory regards the plain as an ancient sea bed elevated by one of the volcanic movements common on that coast, and then desiccated. The nitrate of soda is set down to the oxidation of immense masses of seaweed present in the original sea, the salt of which has provided the necessary sodium base. The chief argument in support is the presence of a small amount of sodium iodate in the crude caliche, seaweed being known to contain iodine. But such a theory is as impossible on chemical grounds as it is untenable geologically. It involves in the first place an extravagant amount of seaweed, and our knowledge of the nitrification process is quite opposed to the idea that it would take place in a rapidly concentrating medium containing common salt. Nor have we any reason to suppose that salt would supply a base for nitrification, even if its hydrochloric acid could be turned out, the liberated acid would at once suspend the process. And again if the iodates are to be taken as indicating seaweed, why are not bromates also present in the caliche, since both bromine and iodine are associated in seaweed.

A much more probable theory is that the deposit represents the desiccated residues of fresh water streams flowing off the Corderillas, containing nitrates and other salts derived from old rich soils or rocks on the heights. The evaporation of such waters for a long period of progressive desiccation would result in the accumulation of the dissolved salts in the dry region over which the waters formerly spread when the rainfall was greater. The occurrence of iodine cannot be explained until more is known as to the amount of this element present in the waters and soils of the Corderillas.

The only other deposits of nitrate of soda which assume any economic importance are those which occur in Upper Egypt, where certain shale beds of Eocene age, outcropping on both sides of the Nile between Qena and Assouan, contain enough sodium nitrate to make the clay worth carriage as a manure, known locally as "tafla." Analyses of a series of these shales by Mr. F. Hughes shows an average of 6·7 per cent. of nitrate of soda associated with 10·1 per cent. of sodium chloride, and 5·4 per cent. of sodium sulphate. The material is disseminated throughout the whole bulk of the clay, and as this is not permeable to any extent by water the nitrate can hardly be due to infiltration, but must have been formed in situ; a conclusion which is much strengthened by the fact brought out by Mr. Hughes's analysis that small quantities of nitrogenous organic matter, ammonia and nitrites, are also present in the extract from the clay.

In all probability the nitrates in these shales represent the results of nitrification of a mass of organic matter originally contained in the deposit, but until further data have been accumulated as to the depth to which the nitrates extend, and their replacement or not by unoxidised organic nitrogen compounds at depths beyond the access of atmospheric oxygen, it is impossible to say whether we are dealing with recent or what might be termed fossil nitrification, or again whether there has been any concentration of the salts in the surface layer analysed.

In any case these Egyptian deposits give a clue to the possible origin of the Chile beds by the washing out similar strata (and the Corderillas consist of rocks of recent age) into a rainless area where the salts are accumulated by evaporation.

The two deposits present this common difficulty, that the deposit is nitrate of soda instead of nitrate of lime, the usual result of nitrification in soil; again both are associated with a preponderance of sulphates over chlorides, a fact which seems to put any marine origin out of the question. We are, however, dealing with typically arid conditions, and in all parts of the world sodium salts are characteristically abundant in the soils and rocks of areas of small rainfall; indeed, sodium carbonate is always found in such cases, and this would form the base for nitrification. At the same time, similar oxidising processes to those which give rise to nitrates would convert the sulphur of the organic matter to sulphates. But really to settle the problem of the origin of the Chile deposits of nitrate of soda, an examination is required of the salts in the rocks of the Corderillas, the drainage from which would find its way into the plain of Tamarugal.

As a manure, nitrate of soda is of course treated as a source of nitrogen. It is not sufficiently realised how valuable the soda

base may be. This is not because soda is in any way necessary to the nutrition of the plant, but because of the action of any soluble salt upon the insoluble potash compounds in the soil. The potash of the soil is due to the partial weathering of double silicates like felspar, into clay, which is not to be regarded as pure kaolinite, Al_2O_3 $2SiO_2$ $2H_2O$, but as containing a certain proportion of zeolitic bodies intermediate between felspar and kaolinite—hydrated double silicates containing potash, soda, magnesia, and lime combined with alumina and silica. Any soluble salt, and particularly a soluble soda salt, will react with these zeolites and exchange bases to an extent depending upon the relative masses of the two bodies, hence nitrate of soda acts on the clay in the soil and brings a little potash into solution. To such an extent does this action take place, that in practice a dressing of nitrate of soda on any but the lightest soils will dispense with the necessity of any specific potash manuring even for potash-loving crops.

This is well illustrated in the Rothamsted experiments (see Table XI.) upon mangels, if we compare the yields on the plots receiving equivalent amounts of nitrogen as nitrate of soda, sulphate of ammonia, and rape cake, both with and without potash. The table refers to the season of 1900, the 25th year of that series of experiments, when it might be supposed the potash in the soils of the plots receiving no potash in the manure must have become thoroughly exhausted :—

TABLE XI.

Plot.		With Nitrate of Soda.	With Sulphate of Ammonia.	With Rape-cake.
		Tons.	Tons.	Tons.
6	Superphosphate and potash	29·6	28·2	29·4
5	Superphosphate only	28·3	12·0	14·9

The plots receiving potash all give about the same yield whatever the source of nitrogen, but on plot 5 without potash the yield is only maintained on the nitrate of soda plot; on the other two the plant is neither supplied with potash by the manure, nor is the soil forced to give up its reserves as it is by the nitrate of soda alone, and the yield declines by one-half or more. In twenty-five years, then, the use of nitrate of soda alone has enabled the soil to supply a mangel crop with the large amount of potash it wanted, though the store of potash in the soil apparently soon becomes exhausted when a manure is used which cannot bring it into solution. With other crops the same results are manifest, though not so quickly as in the case of mangels. For example, we may compare the yield of barley (Table XII.) for successive ten year periods, and to eliminate seasonal influences the yield of each plot will be calculated as a percentage of that on the completely manured plot receiving nitrate of soda.

TABLE XII.

BARLEY GRAIN, HOOSFIELD, ROTHAMSTED.

Plot.		10 years, 1852-1861.	10 years, 1862-1871.	10 years, 1872-1881.	10 years, 1882-1891.	10 years, 1892-1901.
4 N	Nitrate, superphosphate and potash	100	100	100	100	100
2 N	Nitrate and superphosphate...........	98·0	100·2	99·5	105·7	101·4
4 A	Ammonia, superphosphate and potash	92·4	93·7	97·2	100·7	100·8
2 A	Ammonia and superphosphate	91·4	97·8	96·0	90·8	77·8

It will be seen that when the manure contains potash the ammonia salts yield practically the same crops as nitrate of soda. When the nitrogenous manure is nitrate of soda the omission of potash causes no dimnution in the yield; but with ammonia salts and no potash the crop after the third decade becomes unable to satisfy its potash requirements from the soil alone and the yield declines. In other words nitrate of soda has dispensed with the necessity of a potash dressing, which is wanted when sulphate of ammonia is the nitrogenous manure.

One of the most characteristic effects of the use of nitrate of soda as a manure, either repeatedly or in any quantity, is its deleterious effect upon the texture of a heavy soil; farmers have repeatedly observed that the land remains very wet and poaches badly if it is at all disturbed before it has dried. Market gardeners in particular, who manure heavily with nitrate of soda, have found this destruction of the tilth a serious drawback to its use. The cause has usually been put down to the hygroscopic character of nitrate of soda; since the salt itself readily attracts moisture from the air and will even liquify spontaneously, it is considered that it keeps the land moist for the same reason. But the extra amount of mois-

ture that could be held in the soil by a few hundred-weight of nitrate of soda would be wholly imperceptible when distributed through the hundred tons or more which the top inch of soil weighs per acre, even if the application of nitrate of soda persisted near the surface and were not quickly washed down in the soil. Some of the Rothamsted plots in the Barnfield growing mangels, where very large amounts of nitrate of soda have been applied year after year for the last fifty years, show this deterioration of tilth in very marked fashion, the land being intolerably sticky after rain and drying into hard intractable clods, so much so that it is very difficult to secure a plant of roots unless the season is favourable. Determinations, however, of moisture in the surface soil do not show any sensible difference between these plots and those working more kindly, so that we must put aside the idea that there is any direct attraction of water by nitrate of soda remaining in the soil. The explanation appears to be more complex. When a plant is feeding upon a neutral salt like nitrate of soda it takes up rather more of the nitric acid than of the soda, leaving some of the soda in the soil combined with carbonic acid excreted from the root. Water cultures in which plants are grown with nitrate of soda will actually become alkaline to test paper from this cause. Now a very small quantity of a free alkali like carbonate of soda has an altogether disproportionate effect upon clay; the clay is deflocculated, *i.e.*, the little aggregates of very fine particles which cause the clay to crumble down when dry and to allow water to drain through it, are immediately resolved into their finest state of division, and all the characteristic properties of clay are accentuated. Deflocculation is effected mechanically whenever clay is puddled or worked in a wet condition, and all the features of puddled clay, which is both retentive of water and impermeable by it, which shrinks greatly in drying and then holds together with extreme tenacity, are found in these soils when the deflocculation is brought about by a little dissolved alkali. The fact that such deflocculation has taken place may be illustrated by a very simple experiment. Here are two large jars, each containing three litres of distilled water, in which has been shaken up one gram of the Rothamsted clay loam, in the one case from a plot manured with nitrate of soda, in the other, from the adjoining plot receiving ammonia salts. It is already obvious how much longer the nitrate of soda jar is going to be before the sediment has all deposited, which means that the soil under these influences is kept in a more fine-grained and less flocculated condition. Collateral evidence is furnished by some of the other Rothamsted plots; for example, when the tile drains beneath the wheat plots run, the water percolating from below the nitrate of soda plot is always slightly turbid with fine suspended clay material, while the water from the other plots is clear. This removal of the finest material from the nitrated plot has been so persistent during the fifty years or so of experiment on this field, that it is now even perceptible in the analysis; it has only been possible because of the deflocculation brought about by the nitrate of soda manuring.

Again, the soil of these pilots receiving nitrate of soda is found to be losing carbonate of lime to the water percolating through it at a lower rate than the soil of the unmanured plot; this is because the production of a free base by the plant's own growth has, to a certain extent, saved the carbonate of lime in the soil from attack. The following Table (XIII.) shows the annual average rate of loss of carbonate of lime for the last

TABLE XIII.—Calcium Carbonate in Broadbalk Wheat Soils.

1st Depth (1-9 inches).

Plot.		Per cent. in fine dry soil.		Loss per acre per annum.

7	Complete minerals and 400 lb. ammon. salts	3·82	2·25	1010

forty years from some of the chief plots of the Broadbalk field; it will be seen that the nitrate of soda has reduced the loss of carbonate of lime from the soil. The bad texture of the land induced by the use of nitrate of soda is not easily removed; lime is of no service in this case, because it only adds another alkali; a better remedy is to be found in the simultaneous application of an acid manure like superphosphate. Or a mixture of sulphate of ammonia with nitrate of soda might be employed; for, as will be seen later, sulphate of ammonia acts on soil like an acid, hence a mixture of the two manures ought to

make a better source of nitrogen than either alone.

The great rival of nitrate of soda is at present sulphate of ammonia, of which over 200,000 tons are annually produced in this country. The source of origin is coal, which contains about 1·5 to 2 per cent. of nitrogen derived from the original vegetable matter giving rise to the coal. When coal is subjected to any destructive distillation by heat, as in the process of gas-making or even when it is burnt, about fifteen per cent. of its nitrogen is given off as ammonia, which may be recovered from the gases by simply washing them with water. The ammoniacal gas liquor thus produced is redistilled into sulphuric acid and the sulphate of ammonia crystallised out; the commercial salt resulting contains about 20·5 per cent. of nitrogen. Not only gas works, but blast furnaces, coke ovens, shale oil works, &c., are now arranged to recover this valuable product of the coal, and the accompanying Table (XIV.) shows the current output from each of these sources.

As a nitrogenous manure, sulphate of ammonia is practically as effective, nitrogen for nitrogen, as nitrate of soda; it is also to all intents and purposes as rapid in its action, for the process of nitrification, which generally precedes the utilisation of the ammonia by the plant, takes place very rapidly in suitable soils. The fact is well illustrated in the following Table (XV.), showing the composition of the water draining from one of the Rothamsted wheat plots to which a mixture of sulphate and chloride of ammonia had been applied on October 25th, followed the next day by heavy rain, so that on the 27th the drains began to run. It will be seen that at this early date the ammonia had not been wholly caught up by the soil, so that a little found its way into the drains; at the same time, however, the proportion of nitrate has been enormously increased, due to immediate nitrification, and the later runnings of the drains in November and December show that the ammonia salts were being rapidly oxidised and removed from the soil as nitrates.

But though the yield produced by nitric and ammoniacal nitrogen is much the same, with a little advantge on the side of the nitrate, there are certain specific differences in the action of the two manures which are worthy of examination. It has been already explained that the soda base in the one case is of some service in liberating the stock of potash in the soil; the fact that in sulphate of ammonia the nitrogen is combined with an acid, and contains no fixed base causes the manure to be positively harmful on certain soils. When sulphate of ammonia is applied to the soil the first action is an interchange between the ammonia and some of the bases in the soil, the ammonia takes the place of an equivalent amount of lime and magnesia in the zeolitic double hydrated silicates in the clay, but finally the reaction mainly falls upon the calcium carbonate in the soil, ammonium carbonate being formed as a preliminary to nitrification and calcium going into solution as calcium sulphate. Referring again to the analyses of the Rothamsted wheat soils, it will be seen that the long continued use of ammonia salts has reduced the proportion of calcium carbonate below that of the unmanured plots by amounts which are approximately those to be expected if a reaction of the nature—

$$(NH_4)_2 SO_4 + CaCO_3 = (NH_4)_2 CO_3 + CaSO_4$$

alone took place.

The Rothamsted wheat soils started with sufficient calcium carbonate to withstand this loss, but on soils initially poor in calcium carbonate its removal by sulphate of ammonia soon induces a condition approaching actual sterility. The best example is afforded by the experimental plots on the farm of the Royal Agricultural Society at Woburn, where the soil is sandy and only contained at the outset 0·087 per cent. of calcium carbonate. There, through the continued use of ammonia salts as manure, the soil refuses to grow barley any longer, though the former fertility is at once restored by the application of a dressing of lime. At Woburn, the soil of these plots receiving ammonia salts is actually acid to litmus paper, and a similar condition prevails on some of the grass plots at Rothamsted, where the soil, unlike that of the wheatfield, is deficient in calcium carbonate. The origin of this acid reaction is not exactly easy to understand, for there is never any production of acid by the mere reaction of sulphate or chloride of ammonia with any of the constituents of soil—clay, humus, or silica. As far as the investigation has yet proceeded the acid reaction is due to the attack of soil organisms, chiefly fungi, upon the ammonium salts, the ammonia being withdrawn to leave the acid free. Although, under ordinary farming conditions, an actually acid reaction is not likely to arise through the use of sulphate of ammonia, the experiments at Woburn and Rothamsted clearly indicate that it is not a desirable source of nitrogen for soils which are deficient in calcium carbonate. The reaction of ammonium salts with the soil, resulting in the withdrawing of the ammonia from solution, gives a clue to the difference in both the yield and the character of the crop when grown with sulphate of ammonia and nitrate of soda respectively. On the grass plots at Rothamsted, for example, where the manuring has now been repeated year after year for fifty years, very distinct types of herbage have associated themselves with the two manures. Putting aside the prevalence of sorrel as due to the acid conditions also brought about by the ammonia salts, the characteristic grasses are of shallow-rooted habits, *e.g.*, sheep's fescue and sweet vernal grass, while the nitrate of soda has favoured deeply-rooting grasses like the soft brome. Actual examination of the subsoil shows that the roots have penetrated much deeper on the nitrate of soda than on the ammonia plots; the roots having followed the soluble nitrate down into the soil in the one case, whereas in the other they remain near the surface where the nitrogenous material has been accumulated. We may apply the clue thus obtained to interpret the comparative results given by the two manures on other crops; wheat, for example, a deep-rooted crop, may be compared with barley, which feeds near the surface, and again with mangels, another deep-rooted crop.

TABLE XVI.—AVERAGE ROTHAMSTED CROPS.

,, ,, ammonia .	23·4	42·1	14·86

It will be seen that with the deep-rooting crops, wheat and mangels, nitrogen in nitrate of soda gives a better return than an equivalent amount of nitrogen in ammonia salts, although other disturbing factors, such as lack of potash or lime, do not intervene; with barley, however, the yield is sensibly equal with the two manures. At the time of harvest, the crop grown with ammonia salts is always a little the riper; in the case of barley, this is of distinct value, for it results in a more uniform product of higher quality. With the mangels particularly it is seen that the plants manured with nitrate continue to grow long after those manured with ammonia salts have so completed their season's growth that the leaves are beginning to turn yellow and flaccid. All these differences are explained by the deeper rooting habit induced by the nitrate, the plant is less affected by the drought and the changes of temperature incident to autumn, growth is more prolonged, with the corollary of a larger yield but a later and less uniform maturity.

One other factor may also contribute to the general superiority of nitrate of soda. It must not be forgotten that when a nitrogenous manure reaches the soil there will be competition for it between the plant's roots and the mass of living organisms present in the soil, nearly all of which required combined nitrogen for their own development. Some of these organisms, like the nitrification bacteria, are wholly useful. Others cause permanent loss by liberating some of

the nitrogen in the form of gas, but the majority simply withdraw the soluble nitrogen for a time from circulation, building it up in their own tissues. The immediate result is, however, a lessened availability of the manure, and this loss will fall far more upon ammonia compounds than upon nitrates, which are not so generally utilisable by the organisms found in the soil.

It is generally assumed that since nitrate of soda is not retained by the soil, whereas ammonia salts are, the former is a manure better suited to dry seasons and climates, whereas under wetter conditions there is less danger of the latter washing out of the soil. This view, however, forgets that if the ammonia salts are to feed the plant they must be nitrified, and that the calcium nitrate produced is just as likely to be washed down in a wet season. Indeed, the Rothamsted results do not bear out the popular idea. In exceptionally dry seasons there may be some advantage from the use of nitrate of soda because of the deep-rooted habit it induces, but the advantage is still more pronounced in seasons of excessive wet. Taking an average of the wet seasons against the dry, the ammonia salts do better in the latter. Probably the nitrification of the ammonia salts is checked in wet seasons when the temperature is low, and when also aëration is deficient through the repeated saturation of the soil.

It has been assumed that nitrification is a necessary preliminary to the utilisation of ammonia salts by the higher plants, but this point of view is probably too sweeping. Mazé and other investigators have shown for laboratory cultures that plants may feed directly upon the ammonium radicle; and on the Rothamsted grass plots we have evidence that such an action is taking place on a large scale. It has already been mentioned that the soil of the plots constantly receiving ammonium salts has developed an acid reaction, on which, however, a luxuriant vegetation is still maintained. Yet the action of the nitrifying bacteria is suspended by a very small degree of acidity in the medium, and examination of these soils shows them to be almost devoid of nitrates down to the depth of three feet, and even incapable to giving rise to nitrification when seeded into a suitable medium. It is certain that in the soil of these plots nitrification, if not entirely suspended, is reduced to such small proportions that it cannot account for the nitrogen taken up by the crop.

The problems presented by nitrate of soda and sulphate of ammonia are so many and interesting that but little time is left for the discussion of the many important fertilisers in which the nitrogen is present as some organic compound. Of these fertilisers, Peruvian guano is perhaps the oldest and most widely known; news of the deposits was brought to Europe by Alexander von Humboldt in 1804, but it was in 1839 that a small consignment of two tons first reached Liverpool, to be followed the year after by a cargo. The demand increased so rapidly that by 1845 the shipments for the year had reached nearly 300,000 tons. The origin of the guano deposits will be considered in a later lecture; it is sufficient in this place to say that the proportion of nitrogen a guano contains depends upon the character, mainly upon the age, of the deposit from which it is worked. In the various grades in comm;e the nitrogen will vary from as much as 18er cent. in the finest Chinchas guano, dov to 2½ per cent. in the so-called phosphatic gnos, the grade usually met with containing or 7 per cent. The great virtue of Peruvianuano, which distinguishes it from most of thother fertilisers, is the varied state of combinion in which the nitrogen is found; the origkl deposit probably contained little beyond uc acid and proteid nitrogen, but by the pross of decay, which has already set in, a nuner of compounds have been formed, including; the following analysis (Table XVII.) shows, nitr. e.

TABLE XVII.—ANALYSIS OF CHINCHAS GUANO, 1897.

	Per cent.

Total	9·29

salts of ammonia, urea, uric acid, and other more insoluble compounds of an organic nature. Thus while some of the nitrogen is immediately available, other compounds are less active and must undergo some bacterial change in the soil before they are ready for the plant. The plant is in consequence fed steadily and continuously without being presented with an

excess of nitrogen at the earlier stages of its growth; furthermore, whatever changes of temperature and water supply take place to stimulate or check the growth of the plant, they will have a precisely parallel effect upon the bacterial changes which break down the compounds of the guano into plant food. It is found by experience that a plant supplied in this way with nitrogenous food, as it needs it, is generally healthier, and gives rise to produce of higher quality than one which has had an overplus of food in its earlier stages.

Besides the true guanos, of which smaller supplies reach this country from some of the islands off the South African coast, there are a number of other products, the *débris* of certain food-preparing processes, sometimes called guanos, which agriculturally behave in a very similar fashion. For example, in the making of cod-liver oil and in various fish-curing processes, large residues of fish offal are obtained, which are desiccated, ground to a powder, and sold as fish guano. The percentage of nitrogen will vary from nine down to five, of phosphoric acid from five to ten. Similar products, known as meat guanos or meat meals, are prepared by manufacturers of meat extracts, tinned meats, &c., the whole of the animal not otherwise utilisable being dried and ground down. The composition of these meat products again will vary from as highly nitrogenous a material as pure dried blood with 12 per cent. of nitrogen to mere bone meal with not more than 3 per cent. Another class of organic nitrogèn fertilisers are of vegetable origin, the residue of seeds from which the oil has been extracted, and which for some reason or other are unfit for consumption by cattle. Of this class of bodies the best known here in England is rape dust, the meal from extracted rape seed, containing about 5 per cent. nitrogen with about half as much phosphoric acid. In India and other tropical countries castor cake, the residue from which castor oil has been expressed, forms a good and cheap source of organic nitrogen. Another important class of nitrogenous fertilisers embraces all the industrial waste of manufacturing processes dealing with wool, silk, fur, and other materials of animal origin, but not, however, cotton, linen, or hemp residues, for they contain no nitrogen. In general these waste products are termed shoddy, and their composition is purely a matter of origin. Pure wool contains 18 per cent. of nitrogen; shoddies having a woollen basis may contain as much as ten or as little as three per cent. of nitrogen.

These organic nitrogenous fertilisers have each their own peculiarities, though they have never been studied in detail like sulphate of ammonia or nitrate of soda, but they have certain properties in common. In the first place, they are more slowly acting and less available to the plant than the two manures just specified, the rapidity of their action depending both on their composition and their mechanical condition, especially the fineness of their division. Peruvian guano and dried blood would come at one end of the scale, material like ground hoofs and horns or leather at the other. The more slow acting a nitrogenous manure is the greater is the proportion that will be practically wasted, inasmuch as it will escape recovery not only in the crop to which it was applied, but in all succeeding ones. At Rothamsted, where farmyard manure is applied year after year, not more than 26 per cent, of that applied to the wheat during the last fifty years has been recovered in the crop; where the crop has been mangels, the proportion recovered has reached 31 per cent. There is, of course, a great residue left in the soil of each of these plots; indeed, other experiments at Rothamsted show that after forty years some of the nitrogen applied as farmyard manure is still coming out in the crop. However, when the farmer has to wait as long as forty years he practically does not recover it at all, hence slow acting manures are inevitably wasteful. Various tables have been drawn up showing the relative activity of the various nitrogenous manures, but these we owe to continental observers and they are entirely based upon experiments in pots. For this purpose pot experiments are quite untrustworthy; the few existing field experiments tend to show that the activity and therefore the manurial value of these organic nitrogen compounds, even of such a material as shoddy, have been largely under-rated. The Rothamsted experiments upon barley and mangels would show that rape dust is almost as active a source of nitrogen as sulphate of ammonia, the crop recovering quite as high a proportion of the nitrogen applied; other experiments confirm this view based on long-continued trials by showing the effectiveness of rape dust in a single year's trial. Discounting, however, the prevailing false impression, there still remains the fact that these manures are, on the whole, more slow acting and less perfectly recovered in the crop than are nitrate of soda or sul-

phate of ammonia. Nitrogen for nitrogen they should be therefore less valuable, hence it is surprising to find that, putting aside the shoddies, the unit of nitrogen always costs more in organic than in inorganic combination. What, then, is the origin of this strong prejudice of the farmer in favour of an organic source of nitrogen, a prejudice which is further seen in the common description of nitrate of soda and sulphate of ammonia as stimulants or even "scourges" of the soil rather than plant foods. Of course no purely nitrogenous substance is a complete manure, and cropping with one alone must eventually exhaust the land in phosphoric acid or potash, but as has already been shown, the reserves of such materials in the soil are so large, that long-continued cropping would be needed to deplete them seriously.

Some other source must be found for the farmer's prejudice, and its true cause is probably the manner in which organic manures improve the tilth of the soil, whereas sulphate of ammonia and particularly nitrate of soda injure it. The importance of this factor of tilth will be more realised when we remember that nearly the whole of the farmer's labour in spring is directed towards attaining a fine seed-bed for such crops as barley and roots. Furthermore, if the weather conditions are adverse to the start of the crop, the eventual yield will depend more upon the condition of the seed-bed than upon any other factor.

The potent effect of organic manures in promoting a good tilth is very clearly shown by the Rothamsted experiments upon mangels, where the nitrogenous manures are nitrate of soda, sulphate of ammonia, and rape cake respectively. In a good season the nitrate of soda is perhaps the most effective manure, but taking an average over the whole period, rape cake shows a great superiority, simply because of the difficulty of getting a full plant upon the other plots. Though all are cultivated in the same way and at the same time, the condition of the soil has become so bad where purely inorganic manures have been used, that only in favourable seasons is what a farmer would call a good plant obtained on the nitrate and the ammonia plots, whereas the rape cake plot crops regularly enough. On three occasions the plant has completely failed on the ammonia and nitrate plots. Even in the other years there are great deficiencies, as shown by the average number of plants counted on each plot.

TABLE XVIII.—ROTHAMSTED MANGELS, 1876-1902.

Plot.	Manures.	Average Crop per Acre.	Average Number of Roots per Plot.
		Tons.	No.
	Complete minerals		
4 C ..	with Rape cake	21·3	17·474
4 A ..	„ Ammonia-salts ..	14·9	14·802
4 N ..	„ Nitrate of soda ..	18·0	14·130

In ordinary farming, the effect upon the soil is never likely to become so pronounced as in these experiments at Rothamsted, but without doubt a considerable element in the extra value which the farmer sets on organic nitrogen must be put down to its improvement of the texture of the soil, a factor the farmer rightly regards as of the first importance.

APPLIED ART SECTION.

Tuesday evening December 18; LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, in the chair.

The CHAIRMAN, in opening the proceedings, said that the present was the first meeting for the session of the Applied Art Section. It was not always easy to find men who if they knew all about their trade were willing to impart their knowledge to an audience. Mr. Okey was not only a practical basket-maker who knew all about basket-making, but was willing—as he was able—to tell his hearers all he knew.

The paper read was—

BASKET-MAKING.

By THOMAS OKEY.

It once chanced that being among a group of young university men at the Whitechapel Settlement, the talk fell upon what craft would be most useful supposing a man were cast upon his own resources on land virgin of human contact. Many were suggested, but it seemed to me that my own craft, that of basket-making, would not be found the least advantageous. For the basket-maker, in primitive communities, has a wide range of activity. He is the house builder, the military engineer, the boat builder, the maker of innumerable domestic utensils, including vessels to hold and heat water. Even in these days of complicated industrial development he

is with us from the cradle to the grave, he makes the first receptacle wherein we are rocked to sleep in our infancy and, in some cases, the house wherein we are laid to sleep, the last sleep of all, in the silent realms of death. The craft is not only important in itself, it has been the cause of greatness in other crafts. It was the parent of all the textile arts; for basket work is literally a weaving process. The willow pattern in old china, the basket capitals and braided mouldings in Byzantine architecture are derived from basket work, and the curious patterns found on some old ceramic ware have been traced to the marks left on the clay by the basket mould which was in use before the invention of the potter's wheel; and to this day wicker shapes are used by the Japanese for their vessels of lacquer ware. The earlier settlers in Rome and in Western Europe generally constructed their houses of osier work plastered with clay, and they raised their defensive walls of the same material. From a letter of Cassiodorus we learn that, in the early sixth century, the Venetians opposed a dyke of twisted and knotted osiers to the devouring fury of the waves.

Some interesting remains of osier dwellings were discovered, in 1877, at Mount Caburn, near Lewes, in Sussex, by Major-Gen. Pitt-Rivers, and are described in Vol. 46 of "Archæologia." The Roman invaders of Britain found boats of osier, covered with the skins of animals, in use, which seem to have been of the ordinary boat shape, although those mentioned by Herodotus, as used on the rivers Tigris and Euphrates, were round, and covered with bitumen.

By the courtesy of Mr. W. P. Ellmore, of Leicester, I am enabled to exhibit a specimen of a boat obtained at a great cost of carriage from the Euphrates valley and exactly similar to those described by Herodotus. The winnowing fan here shown, probably the last made or ever likely to be made in England, is also the property of Mr. Ellmore, and was made some years ago by an old Midland workman.

The word fan in this sense is derived from the French *van*, an osier vessel of wicker, used from time immemorial for winnowing corn in Latin countries and known to the Romans as a *vannus*. The French words for a basket-maker *vannier* and for basket work *vannerie* are still in common use to-day all over France. Littré traces this old word to the Sanskrit *va*, meaning to breathe or to blow.

A very curious survival of the primitive use of wicker work comes annually under my notice in the east of London. At the anniversary of each celebration of the Feast of Tabernacles I am always asked to make at my workshop in Whitechapel a number of basket *succas* or booths under which the poorer Jews sit to carry out their quaint symbolic ceremonies in the back yards of the Whitechapel ghetto.

Before further progress in my subject, let me refer briefly to the material which from time immemorial has been chiefly employed in the art of basket work all over Western Europe, and in temperate climes generally. And I do so on this occasion with the more interest and propriety since your admirable Society, which has done me the honour to ask me to address you to-night, is historically associated with the development of osier culture in this country. From the years 1793 to 1805 I find in your records many references to money prizes and gold and silver medals awarded to successful planters of osiers. The rewards were offered at the instance of the basket-makers of London, and I have no doubt were prompted by the failure of supplies from France and the Low Countries during the French wars, and the disastrous effects of the Napoleonic continental system.

The prizes were offered to the person who between October 1st and May 1st shall have planted the greatest quantity of land, not less than five acres, with those kinds of willows commonly known by the names of Osier, Spaniard, New Kind, and French, fit for the service of basket-makers. Much curious information may be gleaned by perusing your records during the years I have mentioned, as to the methods of culture, terminology, and values of osiers in those days.

The most amazing delusions have and do now prevail as to the origin and provenance of the material used by the basket-maker. I have before me as I write an enquiry from a lady wishing to teach the village lads basket-making, "but who didn't know how to cut the willows from the trees," which were abundant in her neighbourhood. Need I say that osiers are not cut from trees, but from cultivated beds?

It is very generally supposed too, that any poor marshy land is good enough to plant with osiers, and that once planted, little attention is needed. Nothing could be further from the facts. No crop responds more readily to careful husbandry and intelligent cultivation. For the successful raising of the finer sorts, such as are now in demand, good well-

drained upland loamy soil is required, which, before planting, must be well trenched and cleaned; when the "sets" are planted, frequent weeding is imperative, and the ground, if not subject to periodical alluvial floods, should be manured every year.

Mr. John Shirreff, of Haddington, N.B., winner of your gold medal in 1802, had planted clayey loam, which had formerly been under the usual rotation of crops, and several times laid down under pasture. The land had been well ploughed, and manured for planting. Listen to the careful cultivation he practised: in May, the whole bed was hoed over; in June it was again gone over with the Dutch hoe, and left as fair and clean as any garden; in August it was hand-weeded, and some patches were hoed a third time. The result was an excellent crop, which realised £18 10s. an acre. Mr. W. P. Ellmore, of Leicester, has been wont to weed his grounds five or six times in certain years.

If the requisite capital is available, and the conditions which govern productive cultivation are observed, osier growing is a profitable occupation. At Rome, in Cato the elder's time, an osier bed was held to be only less profitable than a vineyard or a market garden, and coming to modern times I am acquainted with one farmer at least in the West of England who was saved from disaster in the bad years of the latter half of last century by the profits on his crops of osiers. It is much to be regretted that so large a proportion of the material used in this country is imported from abroad and not produced at home. In the Board of Trade returns for last year the import values of willows for basket-making amounted to £62,286, an increase of £10,000 since 1900, when the values were first specified.

The farming of osiers is no less healthy and pleasant than profitable. Who that has been present on the grounds when stripping is in progress can forget the sweet fragrance of the whitened rods. "I love sweet odours," writes Aspasia to Cleone in Landor's "Pericles and Aspasia." "Pray Cleone! have you no willows fresh peeled? none lying on the bank for baskets, white, rounded and delicate as your fingers? How fragrant they were formerly! Ah! I shall always love the smell of the peeled willow." But I must not be tempted to dwell on osier growing, and will now briefly refer to one other and not an indigenous material increasingly used by the basket-maker in this country. The mention of cane will perchance evoke bitter memories of pedagogic discipline and the weals and woes of schoolboy days; to the basket-maker it furnishes one of the most valuable of his materials. Until recent times it was employed either whole or split into skeins which will be familiar to all from their use in cane-bottom chairs. About 1880 the central pith of the cane, prepared in long rods of varying sizes, was introduced into England under the terms Cane Pith or Cane Pulp. Its somewhat stringy nature and facility of manipulation have led to its being used for cane-weaving by children and women as well as by the professed basket-maker.

Excellent work of this kind has been produced by some of the women workers, but the economic results are of small value, and the terminology in use is uncouth, confusing, and amateurish. In one handbook, the term "spoke," itself unknown to the professional, is made to do duty for no less than five separate and different strokes. By the trade, prepared cane pith is employed wholly or partly in the making of chairs, tables, luncheon, tea, and other baskets.

A delusion no less amazing exists as to the status of the basket-maker. When I was first appointed examiner to the City and Guilds of London Institute, I found basket work classed with millinery and dressmaking, and in the new edition of the most popular and well-informed books of reference, "Chambers' Encyclopædia," we are informed that "a large number of poor persons are engaged in the manufacture of baskets which are hawked about the streets by their wives and children." It is as one of these poor persons who has earned his living as a journeyman basket-maker for 17 years and a master for 20 that I address you this evening. The fact is that to become an expert basket-maker a considerable native aptitude and long training are required. The basket-maker is in every sense a craftsman; no machinery is used, and the ultimate perfection of shape and beauty of texture depend upon the more or less perfect conception of beautiful form in the mind of the artist, and the power of the fingers to impress such form on a recalcitrant material. Every stroke has a permanent effect on the symmetry of the whole; no subsequent pressure will alter it; it is impossible to mould into good form work that has been ill-shapen in any part of the weaving. The results are as irrevocable as those of actions good or bad in the moral world.

The wages of an expert workman are consequently fairly high, and £2 10s. per week, or even £3 per week I am told, though this has

not come within my own experience, are earned: at coarse work the wages average from 25s. to 35s. per week. A good workman is never out of work; no loss of pay is ever incurred through frost or other climatic disabilities, as in the building trades. The workman is efficient, even in old age; for by an unwritten law, the older men in the shop are given the privilege of the lighter work. An excellent old "square" hand, who worked for three generations of my family, died this year considerably over seventy years of age, and with a little financial help, and his club pay to tide him over temporary ill-health, was able to hold his plank until within a very few weeks of his end. He was the last man I knew who had made, and could still make, the various kinds of the old English reticule.

The Basket-makers' Trade Union, founded in 1816, is one of the oldest and most flourishing of the London unions. Since 1850, the oldest list I have, a very considerable rise in wages has taken place, both in piece and time work; in the latter from 6d. to 9d. per hour, and the employer now finds artificial light instead of the workman. A very great advance has taken place in my time in the social habits and intelligence of the workman. The old hard-drinking, hard-swearing twiggy, groping at his work in a cellar by the dim and uncertain light of a rush-light fixed in a cleft stick and stuck into the wall, has long disappeared; and on entering as president of the Osiers Cricket Club, mainly composed of the younger generation of workmen, to take my place at the annual dinner last year, I at first sight almost doubted whether I should find myself the only person not in broad cloth.

A glance through our old lists is not without its interest to the student of social changes. In all those I posses from 1850 to 1877 the wicker instruments specified as "bug traps" are listed. In 1896 they disappear—an interesting evidence of the increased cleanliness of the community and of the supersession of the old wooden bed by the iron one. The old measurement by nails (2¼ in.) instead of inches has entirely gone. The old yard stick was literally marked with nails. The basket-maker is one of the few remaining workmen who sings and talks at his work, and a basket-maker's shop—at least in the earlier days of the week—holds a somewhat boisterous company. I am bound to say that the wit is often somewhat Rabelaisian, and a modification of Terence's line, "Nihil *feminæ* a me alienum puto," occupies a too large part of the conversation. When working alone, he has opportunity for pensive meditation. One of our fellows, Thomas Miller, the basket-maker poet, was able to beat his music out as he sat on his plank in a little shop in Elliot's-row, Southwark, labouring, as he said, to consort with the muses and maintain a family. He won a modest footing on Parnassus and his well-known poem "The Fountain" (1839), has found a place in the literary annals of England. He was the author of about 45 works in poetry and prose, and won the esteem of Lady Blessington by a present of some productions of his mind and of his fingers, in the form of a fancy basket, containing a selection of his verses. It was at Lady Blessington's house that he met Disraeli who, in later years, obtained for the old poet a pension of £100 a year from the Royal Bounty Fund.

Some surprise may have been evoked by my use of the term artist in connection with a craft so lowly as that of the basket-maker; this is, however, only because the old word has been so distorted in meaning. In days when people cared for beauty, the use of the term *art* or *artistic* to denote anything outside the ordinary products of human activity, was unknown. Dante, when he wishes to emphasise the degeneracy of the citizens of Florence in his days, says that in olden times their blood ran pure even in the veins of the *ultima artista*—the commonest workman. It is because we have lost the thing that we make a fetish of the word. Indeed of all the shoddy rubbish now sold that described as art basket-work is generally of the shoddiest.

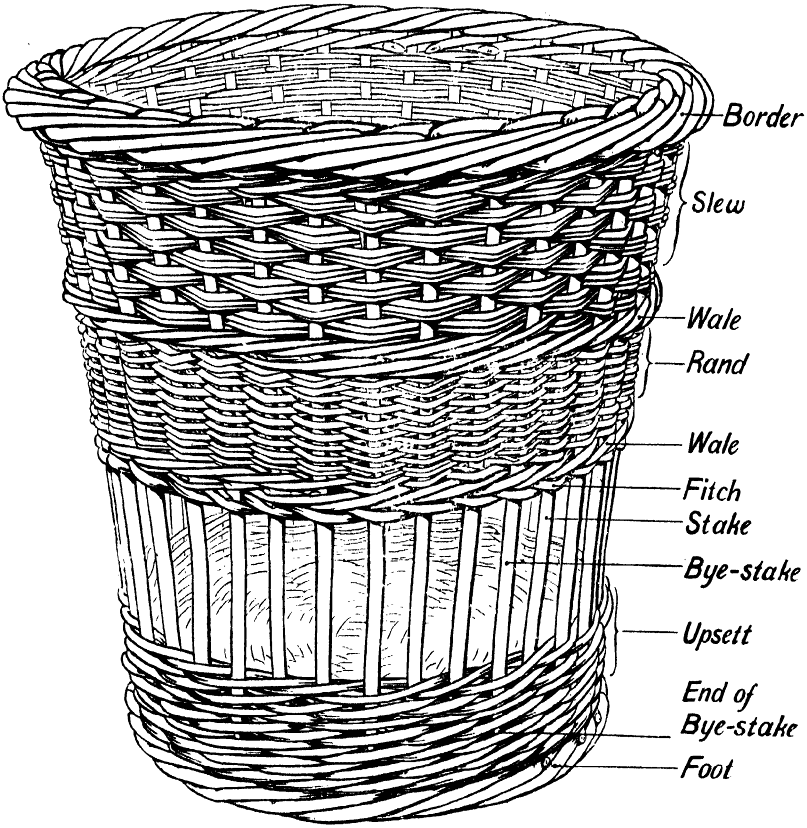
The willows when they reach the workman are known to him as rods, which he roughly classifies as osier and fine. The former is generally used brown for coarse hamper work, and is unstripped; the latter, stripped of its skin, and used whitened or buffed, is employed in the manufacture of the finer classes of work,—buff rods being rods which have been boiled before stripping, and so stained a rich light brown hue, as you see here. The technical terms for the sizes into which the rods are sorted are most ancient and curious. The smaller sizes of brown are known as luke, and the rising sizes as long small, small, threepenny middeboro, and the largest as great. The white is more carefully subdivided, and the smaller sizes are known as tack, short small, long small, &c. Ragged is the rough twiggy stuff which is rejected as valueless for whitening purposes. Having been soaked in tanks the

requisite number of hours or days, the stuff is ready for use. The tools required are few and inexpensive; a shop knife for cutting out; a picking knife for trimming off the rough projecting ends; one or two bodkins for staking up or making handles; an iron for driving the work closely together; a pair of shears for cutting off bottom or cover sticks, and a dog or commander for straightening the sticks that form the rigid framework of square baskets. For finer work the rod is split into three or more skeins by a cleaver; the splits are then successively drawn through a shave to remove the central pith and through an upright to render them uniform in width. This is the full kit. I exhibit here a specimen of each. An ordinary round or oval basket can be made with no other implement than a knife. This paper basket, which I made for the purpose of illustration, I completed with the aid of no other tool than a pocket knife (Fig. 1). The employer provides a lap-board on which the basket is placed while the sides are being filled up, and a block or vice used for gripping the sticks on which the bottoms and covers of square work are woven.

A rod to the workmen has four different parts — the butt, the top, the belly, the back. To make a round basket the workman first cuts off the bottom sticks from the butt end, slipes them and places them cross-wise beneath his feet, and in this position proceeds to weave the bottom. He first binds them together by two rods called slath rods, and gradually opening out the radiating sticks he fills the bottom up to its required width. The first task of an apprentice in my days was confined to making these bottoms—a peculiarly diabolical form of torture known as taking the boy's backbone out. There is a method of making a round or oval bottom in a sitting position by splitting one layer of the cross sticks with a bodkin and inserting the others. This, however, is rarely practised in this country and it is scorned by the English workmen as fit only for women and foreigners. The bottom sticks being cut off (and if the basket is to be a common slewed one) the workman sharpens by two cuts on the back an odd number of stakes which are to form the warp, so to speak, of the sides: these are inserted in the bottom and then pricked up by the point of the knife, gathered into a hoop, and set up or upsetted in the direction of the body of the basket. This being done it is sided up to the requisite depth, the stakes are bordered down, and the projecting tops are cut off. This is known as the belly. If a foot is needed it is now put on by inserting the tops cut off from the stakes alongside the upsetted stakes; the foot rods are waled and then laid down as in a border. A cover is made in similar fashion to the bottom, and handles are fixed by twisting a rod and roping it under and over the border. Note that the plural of foot is not feet but foots. The strokes chiefly used are termed: a slew when two or more rods are woven in together; a rand when one single rod is woven at a time; a pair when two are woven alternately one over the other; a fitch when two are woven alternately one under the other; this last stroke is used for making skeleton work. A wale is three or more rods woven one after and over the other to form a binding or string course. Besides common borders, many other forms, such as plaited, roped, tracked borders, are used.

You will look in vain in any dictionary, even in the New English Dictionary, for reference to these queer technical terms. The etymology even of the word basket is unknown. Much learned stuff has been written in encyclopædias and other works of reference about its derivation from the Latin *bascauda*, and imposing Latin quotations from Martial and Juvenal are cited to prove the connection; but in truth there is no relation whatever between the words, and both Dr. Murray and Professor Skeat are constrained to admit that the origin of the word basket is as yet unknown.

Methods have little changed since primitive times. The oldest wickerwork in existence are two Egyptian workmen's baskets and a fitched papyrus basket, about 4,500 years old, found in an unfinished grave of the fifth dynasty at Deshasheh, and figured in Professor Petrie's report published by the Egyptian Exploration Fund. Mr. T. R. Way has kindly sent down an old Egyptian basket found in a tomb, and on examining it this evening I was interested to find the same strokes—the fitch, the pair, the border, slath, and wale—I had been using yesterday in the making of this paper - basket. Some fitched basket chairs and a basket chariot, preserved in the Etruscan Museum at Florence, are nearly 3,000 years old, and some fitched work by the natives of Tasmania, made before their extermination by the whites, and preserved at Oxford, takes us back to a primitive people only in the neolithic stage of human development. The strokes in these specimens are



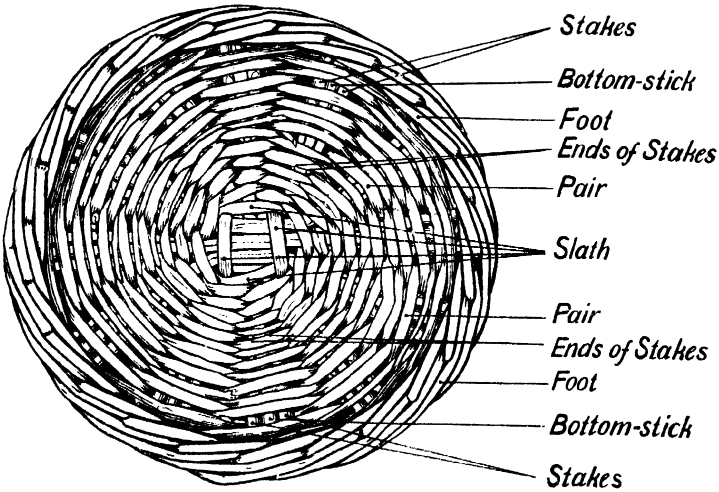


FIG. 1.—CHIEF STROKES IN BASKET WORK.

Engraving ot a waste-paper basket made by Mr. Okey to illustrate the chief strokes used in basket making. It will be seen that the bye-stakes are merely inserted in the upsett, whereas the stakes are driven in at each side of the bottom sticks and pricked up to form the sides. Bye-stakes are only used in fitched work.

the same as those used by the European workman to-day.

In the history of the arts, however, the importance of basket-making is in inverse ratio to the industrial development of a people, and it is among primitive races that the most beautiful work is found.

The Pomo Indian of California* was cradled in a basket, his home was a great thatched basket, his toys were baskets, he ate from a flat basket, and drank from a round one. His meal was winnowed and ground in a basket; his fish and meat were cooked in a basket; his water bucket was a basket; his fish was caught in a basket; when he travelled, his belongings were packed in a basket. If he gardened, his fences were of wickerwork; he trapped birds and game in baskets, and on Lake Clear the art of basket-making was used in making canoes. Until the advent of the white man 50 years ago these strangely remote folk literally had no other vessels, and the number and excellence of her baskets were indicative of the Indian woman's status in the tribe. The time and patience expended are incredible, as much as two years being sometimes required to make one piece of work. Recently a new fad has arisen in America for making collections of these beautiful utensils which have been treasured as heirlooms in Indian families, and large prices have been paid for baskets made by the few squaws who have inherited the traditions and practice of the art. As much as £300 has been paid for one specimen, and it is computed that baskets to the value of £1,000,000 have been drawn from Arizona and California within two years.

Here is a finely woven basket from a poor Italian village near Spongano, in the extreme south. It is made from a local species of flinty sedge, and is sold for 60 centimes (6d.)

Among Eastern natives, the Japanese attained a marvellous degree of excellence in the manipulation of basket-work. The material used, as in the East generally, is bamboo or cane split into skeins. By the courtesy of the South Kensington Museum authorities, I am enabled to show some exquisite Japanese bamboo and rattan ware, and some beautiful work from India and Siam. Nothing can exceed the refinement and art displayed in these admirable specimens. Some excellent modern Japanese work is also shown by the courtesy of Messrs. Liberty and Co.

But the art has not been confined to these peaceful utensils of domestic interest. Of old and among modern savages the shields of warriors and braves have been and are fashioned of wickerwork, either plain or covered with hides; and Xenophon, in his story of the Thirty Tyrants at Athens, relates that the exiled Athenians at the Piræus made to themselves shields of whitened osiers.

A curious development in the use of wickerwork for military purposes took place in this country last year, when the authorities began to use wicker shields of cane pith for the protection of live shells in transit.

During past years the incidence of the work produced in Great Britain has been greatly modified owing to the fiscal changes introduced in the middle of last century. The old English reticule and other small domestic ware have been driven out of the market by cheap and more flashy goods from the Continent. The 27 sizes and styles of English reticule appear for the last time in the London Basket Makers' list of 1850. The last workman I know of who had made such work passed away this very year. The coarse brown osier packing and hampers have also been largely superseded by rough cases and casks made from cheap imported timber. English masters did not all, however, whine for protection against the foreigner; the more enterprising set to work to improve the quality and to develop and enlarge the scope of the manufactured articles. Goods of a higher class were produced, such as finely-made chairs, lounges, tables, luncheon and tea baskets, travellers' hampers, so that the lost ground has been more than regained, and a great stimulus has been given to the cultivation of finer kinds of willows.

To two firms this appreciation and improvement of basket work is chiefly due—Mr. W. P. Ellmore, of Leicester, and Messrs. Scott and Sons, of London. Some evidence of these developments is afforded by a comparison of two lists of wages issued by the London Union of Journeyman Basket-makers in 1865 and 1896 respectively. The former consists of 87 printed pages, the latter of 144, and these more closely set. A very large proportion of this increase is due to the inclusion of work first introduced by Messrs. Scott and Messrs. Ellmore.

By the courtesy of Messrs. Scott and Sons, I am able to exhibit some specimens of excellent London work in the shape of luncheon baskets, &c. By a similar favour from Messrs. Ellmore and Sons, I am permitted to show

* Carl Purdy, "Pomo Indian Baskets and their Makers."

some of their London and Leicester work in these chairs, tables, and linen and luncheon baskets.

The main sources of foreign supplies, which in 1901 reached the value of £264,183 were, in the order of their importance — Belgium, Holland, France, Germany, Japan, and Portugal. A remarkable shifting of values has occurred between France and Japan since 1900. In that year from Japan we imported £8,140 value; in 1904 we had increased our imports from that country to £52,377. From France our imports, which in 1900 amounted to £55,870, declined in 1905 to £27,900—a reduction of almost exactly one half. In those years German imports too declined from £33,155 to £22,892—a decrease of about one third. The greater part of this imported work is of a cheap and gaudy nature, and is produced under economic and social conditions I should be sorry to see reproduced in this country. I am proud to be able to say that our craft here in England has been kept out of the hands of the sweater. In certain villages I visited when seeking work in Germany, I found whole families—father, mother and children—working long hours and seven days a week to earn a collective wage of 10s. I well remember the look of amazement that came over the local merchant when I told him the wages I was earning in England. "Gott im Himmel, höre nur zu!" he exclaimed. We have not, nor ever have had, the lightness of touch and neatness which characterise the best French work such as I have seen in some Parisian workshops, but no continental productions approach our best English work in qualities of shapeliness, strength, and durability. Some few years since I invited a Belgian exporter, who had often and importunately sought to supply me, to visit my workshop in order to inspect examples of the English work he would compete with. I placed before him a finely-made linen hamper and a wine flat. He looked; he touched; he despaired. Then throwing up his arms exclaimed, "Ah! jamais un ouvrier belge ne ferait ça." I never saw that Belgian more.

Some grave misconception exists in the public mind, and not a little due to the action of the associations for the welfare of the blind, as to the nature of our craft. Parents, guardians, and charitable folk have often come to me with the halt, the lame, and the blind, believing that basket-making would form an appropriate means for enabling such afflicted lads to earn a living. Need I remark, after what I have said with regard to the necessary native qualities required, that such belief is almost a vain one. The associations referred to undoubtedly serve a charitable and useful function in the social body, and a certain number of partially or wholly blind workpeople are employed in the making of the common kinds of baskets; but the work thus produced is not commercially remunerative, and the associations depend for partial support on the contributions of the benevolent public and on sales of work produced under ordinary conditions and largely imported from the Continent. The work made by the blind is rarely or never exposed in the windows, at least of the shop in Tottenham-court-road. During the past months I have several times inspected their windows, and all the work exhibited there has been of the ordinary cheap commercial kind, the work produced by the blind, which to the expert eye bears obvious traces of its origin, being kept in the background. The results of this policy are that the public is led to believe that the work exhibited is done by the blind, and owing to sentimental reasons it is sometimes preferentially purchased. Certainly the skill and industry of these poor blind folk is admirable, but the work has generally what we term a sore-fingered aspect. The very kindest and most expensive material must be employed, and supplementary assistance in wages is needed if a living is to be earned.

I have referred to the existence of the Basket-makers' Trade Union. It is not so generally known that a Basket-makers' Company still exists in the City of London, and is one of the oldest of the minor trades guilds. In the report of the Livery Companies Commission, 1884, the origin and early history of the Company is said to be lost in obscurity, and in the proceedings of the Court of Aldermen on the granting of livery it is said to have been from time immemorial. All the books and documents belonging to the Company were kept at the Guildhall, and were totally destroyed "in the great and dreadful fire, together with carpets, silver spoons, and other property." It seems probable, say the Commissioners, that the charter may have met with the same fate. However that may be, the Company now exists by prescription and not by charter. The only ancient clue to its existence, says Mr. Hazlitt, is a record of the time of Edward IV., where it is classed with gold and silver wire-drawers and other

foreigners, and its members are restricted to the manor of Blanche Appleton or Chapelleton, now occupied by Fenchurch-street Station and London-street. It is a curious coincidence that the little basement workshop where I learned my craft, and which has been in the occupation of my family for four generations and more than a century, is No. 1, New London-street, on that very Manor of Chapelleton, where the basket-makers of London were settled in the fifteenth century. There seems little doubt, as this early record implies, that in early times the craft was largely exercised by foreigners outside the city, for in the rules and orders of the Worshipful Company of Basket-makers, made by the Court of Aldermen in 1569, it was enacted :—"Item : Forasmuch as at the present time the good men of the same craft are not able of themselves to serve this honorable city with wares unless they have foreigners and aliens to work for them, for a time, until a convenient number of their own apprentices be brought up, taught, and instructed to serve in the same craft, it shall be expedient that every person now enfranchised, shall and may during the space of five years now next ensuing, and no longer, have and keep such foreign apprentices as they now have, and such other foreigners and aliens, cunning and expert in their said craft, if such person cannot have freeman of the said company to serve him." Well, rules are easily made, but foreigners and aliens both in the City of London and in the country generally are and always have been difficult of regulation. I find that thrice five years had passed and foreigners were still with us, for further orders were issued by the Lord Mayor and Court of Aldermen, in 1585, "that it be lawful to keep in work all these foreigners and strangers that we now have, and from henceforth no more to be received in the said craft, and that whosoever enfranchised in the said craft should presume to set any foreigners or strangers on work, who should have left the City, shall have the penalty of the law." But alas! despite the penalties of the law, the stranger within our gates lived and flourished, for in 1610 further orders were made "that no freemen of this city using the trade of Basket-making or Basket-selling shall at any time hereafter buy any manner of made wares of any foreigner using the same trade but such sorts of made wares as of ancient times have accustomed to be bought of foreigners."

I wish I had more time to deal with the curious rules of this ancient art and mystery of the citizens of London — the summary powers conferred upon the warden to enter the workshops and to search, view and oversee, all manner of baskets, flaskets, scryns, maunds, and all other wares and stuff, and to denounce all such as they found unlawful, not well and workmanlike and strongly made, and wrought with good and seasonable stuff, and bring them to the chamber of the city to be forfeited; the heavy fines inflicted on any person of the said craft or fellowship who should rebuke, chide, or brawl with any other person of the said craft; the stringent rules against hawking wares about the city and suburbs; against enticing or inveigling any other man's servant from him by giving or offering any money called drinking money or giving or offering any wages greater than the usual wages. Suffice it to say that this venerable company was amongst 55 companies assessed for corn money in 1603-4, and that although its income and membership are small, it maintains the hospitable traditions of the City. It cannot be described as a bloated company wallowing in wealth. According to Weale's, "London Exhibited" its income in 1851, was only £10. Its income for the ten years under review by the Commissioners of 1884 is said to have averaged £35 a year, "which is chiefly spent on an entertainment." In the accounts for 1878-9, out of an income of £32 16s. 6d., £26 6s. was spent on the annual dinner; in the next year £36 15s. was spent in the same festive manner. The income is wholly derived from fees, for the company has no house or landed property. The number of members in 1884 was 35 freemen, 59 liverymen. At the present time the freemen number 130. The income for 1892 had risen to £102, and for the past decade the company have granted five money prizes, amounting to £11 in all, to the candidates for examination in the department of Technology of the City and Guilds of London Institute—prizes which, I regret to say, I have not always been justified in awarding, owing to the paucity of examinees and the poor quality of the work done.

Having touched on the matter of examination may I conclude by a comparison between the class system initiated by the County Councils of this land, and the old workshop system of training which has prevailed, and still largely does prevail, in my craft. A lad attends a class once or twice a week taken by a more or less competent teacher. He is one of many lads, and is taught straightway to make a certain piece of work, while all around him are other

lads alike fumbling to obtain some command of their material. Now let me describe the boy's training under the workshop system, by my own experience. And here let me make clear that I am dealing with the practical side only. I have no doubt that under the class system much good does and will result from such theoretical tuition as may be possible in the different crafts. Well, then, at about twelve or thirteen years of age the boy is set to work, at first doing odd jobs of sorting and preparing material. He thus obtains a thorough knowledge of the various kinds of stuff, their due preparation and handling. He probably does much of this in the workshop, and whether he does or not, soon enters the shop, and there among a number of competent craftsmen, his training begins. Truly he does not seem to be actually taught very much, but the very fact of his being in the midst of workmen, each with a greater or less mastery of his craft, and working with that emulation, often unconscious, which inevitably obtains where men work together, is a priceless training which no class can afford. Working in this atmosphere of craftsmanship the lad seems to absorb its spirit and grow in the mystery of his art. For some time he is not allowed to make any piece outright, but at length he is set to work on the simpler articles, say a common round or oval basket, and so he is led from simpler to more difficult work and grows to be, if an observant and tractable lad, a trained workman, for all about him are men whose every stroke is an incentive to greater perfection. It would be impossible for him to answer a set of questions in an examination paper with anything like the readiness attained by a class student. He would be hopelessly beaten at that, but he could turn out a workmanlike and finished piece of work pleasing to the eye and useful to the community. I regret to say that my experience of the results of the class system has not been encouraging. For, in truth, excellency of craftsmanship cannot be taught in an art class any more that a fine literary style can be taught in a composition class; that comes only from a familiarity with the masters of literature and severe self-discipline; and it is even so in craftsmanship. To work among, and be insensibly influenced by, masters of the craft is an essential element in the making of a good workman. What the lad sees in a class-room is a number of his fellows all equally inexpert; there is no atmosphere of good craftsmanship; no sense of excellency to bring forth and ripen the flower of perfect art. This fact seems to me not sufficiently recognised in the new industrial training, and I have therefore thought it not out of place to revert to it before closing. Ladies and gentlemen, you cannot learn to be a basket-maker in six lessons at the Albert-hall nor in a few months at a class-room.

DISCUSSION.

Mr. G. Earle asked why it was considered poor workmanship in England to put spokes through spokes for the base of a basket?

Mr. Okey, in replying to the question, said the method was used for very light work, but English workmen thought it was a feeble way of doing their business, because it was not quite so strong. It was perfectly justifiable to use the method, and it was mere prejudice on the part of the English workmen that it was not used.

Mr. Harrison Townsend remarked that the reader of the paper had described, without going too much into the archæology of the subject, an art and a craft which had been carried on from the Fifth Dynasty down to the present day, and had explained in not too technical language the different methods employed then and now in the craft. He had brought under notice its continuity, and had put forward a very just and fair claim to its being recognised as perhaps the oldest technical and craftsmanlike process in existence. A few weeks ago the speaker had the opportunity of seeing some of the modern basket work of Europe on show at the Milan Exhibition; but the samples and specimens which were exhibited that evening were much finer specimens of art and workmanship than the modern French, Italian, and Austrian examples exhibited in Milan. If it had done nothing else, the paper had shown that there was still one craft which, in its English manifestation, was worthy of all respect, and for that reason he desired heartily to thank Mr. Okey for his instructive paper.

Lieut.-Colonel Allan Cunningham remarked that Mr. Okey had spoken with enthusiasm of his craft, describing it as a handicraft which could be essentially carried out by hand with a few and simple tools, and was therefore very valuable as a home industry. He was afraid, however, it would not be suitable for the unemployed—or, at any rate, for those who were unemployable—because the handicraft evidently required great skill, training, and apprenticeship for its proper accomplishment. Mr. Okey had given a most interesting account of the apprenticeship system in vogue in the basket trade. He was sorry to find that the apprenticeship system was falling out of use in England, very few boys being apprenticed

nowadays. Much higher wages were now offered to boys as newspaper hawkers, runners, and letter carriers, a most unfortunate state of things, because the boys were thus tempted away from learning a handicraft which would be the means of earning them a living in after life. When the boys grew up, they were dismissed from their employment as hawkers and letter carriers, and were unable to earn a living wage. In the eyes of an enthusiast, basket-making was not merely a handicraft, but had been called by the author an art, the basket-maker being an artist. Certainly the specimens exhibited were of a most beautiful character, and brought home the truth of the author's statement in that regard. Even cheap basket work had its uses. Mr. Okey had mentioned two principal materials as being in use in England, the osier and the cane, the former being indigenous and the latter imported. It was a very curious circumstance that an imported material should be capable of being so extensively used, and that such great skill should have been obtained in its use as a trade as to absorb nearly half the quantity of the material grown. Rushes and bamboo were also useful for basket-making. Mr. Okey had referred to the latter, but had not mentioned the great importance of it. In those countries in which bamboo was indigenous, it was a material of extreme importance to basket-makers, all sorts of things more or less of the nature of basket work being made from it. For instance, a sort of basket work formed the walls and floors of many huts. The bamboo was simply beaten flat, and then roughly woven together to form the walls and the floors. All sorts of rough baskets were made from it, the coarser qualities only being made because it was not the kind of material that lent itself to fine weaving, being too harsh. One of the most interesting parts of the paper to the non-professional man was the part dealing with the ancient history of the basket, the slides exhibited showing the forms of ancient basket work being most interesting specimens. The Chairman, in inviting discussion had hinted that possibly members of the audience might desire to correct the author in some of the statements he made. Personally he thought that was impossible, because he could only give unqualified praise to Mr. Okey for his paper.

Mr. H. B. WHEATLEY desired to refer to two points mentioned by Mr. Okey. The illustrations of basket work in architecture taken from Ruskin's "Stones of Venice," were very valuable, and he might note the fact that much of Saxon art consisted of an imitation of basket work. It would probably be within the knowledge of those present that the ornamentation of most of the designs on the Saxon stone coffin tops in Peterborough Cathedral, had their motive in basket work. The second point was, that he thought the "foreigners" to whom Mr. Okey had referred could hardly be called aliens, because he believed the term "foreigner" merely meant someone not a freeman of the City of London. In all documents of the City Companies, the term "foreigner" meant an individual coming from outside the City, but in certain instances the word "stranger" might represent an alien. He was sure that Mr. Okey's interesting and valuable paper dealing with the history of an art of which very little was known had been highly appreciated.

Mr. H. A. LEE, as a member of the London Union of Journeyman Basket Makers, desired, on behalf of his shopmates, to thank the Society for being allowed to be present and listen to Mr. Okey's interesting paper, which was true to life in the trade as they knew it.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his most interesting and helpful paper, remarked that his own interest in basket-making was mainly in its connection with pattern weaving. Mr. Okey had called basket-making the parent of weaving. It was undoubtedly the primitive form of weaving; some people even called it the primitive form of all pattern design, and he was not sure that that was not the case. He had been particularly interested in what the reader of the paper had said about his craft. It was delightful to hear that a man could nowadays earn a good living at basket-making, and that there was still a craft in existence where a man would sing at his work. Apropos of Mr. Okey's statement that his family had sprung up in the district where basket-making was made, and had been there for many generations, and to his reference to aliens, he could not help wondering whether the author, who spoke so fluently in many languages, was one of the descendents of those very desirable aliens. He was in entire agreement with Mr. Okey's remarks on the difference between class and workshop teaching. A handicraft could never be taught in a class as it was in a workshop. Technical classes, as Colonel Cunningham had said, were only a very poor attempt to make up for the lack of apprentices. It was the fact that every man had to learn his trade, and a trade could not be learned, as Mr. Okey had very rightly said, in six lessons at the Albert Hall. One reason perhaps why the pupil in classes did not learn a trade as well as in the workshop was that in the class, where he might be doing very little that was to any purpose, he was doing it with others who did it perhaps to less purpose still. He could therefore imagine himself a clever fellow, he got a swelled head, and that meant the end of him as a workman. On the other hand, in a workshop a youngster worked with older workers, and it was no use giving himself airs or fancying he was a great man. If he did so he would soon get it knocked out of him, and be brought very quickly to his level. The basket work exhibited was for the most part very good from the point of view of design; but he would like to ask whether there was any reason why basket work, as it was

seen generally in the form of chairs and tables, should be so wobbly, and why a little more quiet and restraint in the forms of basket work could not be introduced. He did not see why basket work should be made in the form of Austrian bent wood.

The resolution of thanks to Mr. Okey was then put, and carried unanimously.

Mr. OKEY, in reply, thanked the audience for the vote of thanks, stating that he was very pleased to find that his paper had aroused so much interest. With regard to Colonel Cunningham's remarks, it was an undoubted fact that a good many rush baskets were made, and he ought to have referred to them in his paper. It was not, however, a very important section of English work. A good many rush baskets were imported from Italy but they were not very valuable. Plaited rush was very much used in the manufacture of such articles as luncheon baskets and chairs, but he did not bring any specimens with him, because they gave one the impression of looking rather "gouty" as it was called in the trade. Personally he did not like plaited rush work very much. With regard to bamboo, he was always amazed every time he saw Japanese work to find what could be done with that stubborn article. Nearly all Japanese work was made out of bamboo skeins. Mr. Wheatley had referred to the use he had made of the word "foreigner." The point which had struck Mr. Wheatley had also struck himself when he first saw the reference to the word in the excerpt from the statute of Edward IV.; but when he found that the words "foreigners" and "aliens" were also used a few years later, it seemed to him there could be no doubt they did actually mean a foreigner. There was no doubt that, all through the history of basket-making, a good deal had been learned from foreigners. From mediaeval times even up to the present day the word "foreigner" in certain parts of England simply meant a stranger from outside. For instance, in a hop picking village where he lived some time ago, the native hop-pickers spoke of the people who came in from outside as foreigners or strangers. He had endeavoured to get a sight of the statute of Edward IV., but as Mr. Hazlitt did not give the reference in his book he could not find it. Of course everything depended upon the Norman French or Latin word used to convey the term "foreigner." With regard to the Chairman's point as to the form of basket chairs and tables, he did not at all defend the attempts made to imitate Austrian bent wood, but that terrible thing, commercialism, governed all trade productions. Certain makers wished to improve on the patterns of other makers and to do something else, and that was responsible for what had occnrred. The actual craftsmanship, however, was very good, the basket work in the chair and linen basket exhibited being of the most excellent character.

GLEANINGS FROM THE BRITISH RAILWAY RETURNS FOR 1906.*

There is very little of an absolutely new character in the returns for 1905, which, save for some slight addional information respecting electric railways, follows the lines of immediately preceding reports. If the present commission on railway statistics makes any drastic recommendations, it is difficult indeed to conceive how such recommendations can bear any fruit until the returns for 1907 are available. Regarding the returns for 1905 as a whole, these present one or two encouraging features, manifesting the fact that attention is being given to such subjects as the loading and idle mileage of goods trains. Otherwise slight increases in capital outlay are to be chronicled, accompanied by slight increases in gross earnings, and the accustomed decrease in the second-class passenger. Taking these and other matters in their order, the following facts are of note:—

Capital.—The total paid-up capital at the end of 1905 amounted to £1,282,800,000, an increase of £14,300,000 over 1904. Of the total capital, £194,300,000 represents nominal additions due to the consolidation, conversion, and division of stocks. The average dividends paid on the various classes of capital in 1905 were almost exactly the same as those paid in 1904, being approximately 3¼ per cent. on the ordinary capital, 3½ per cent. on the preference, 4 per cent. on the guaranteed, 4 per cent. on the loans, and 3½ [per cent. on the debenture stock. The average rate of dividend or interest computed on the total capital, as it would have stood if no nominal additions had been made thereto, was 4·05 per cent. as compared with the rate of 3·43 per cent. mentioned above. In like manner the proportion of net earnings to capital, exclusive of the amount of nominal additions, is 3·99 per cent.

Traffic Receipts from Passenger Traffic.—The passenger traffic earnings amounted in the aggregate to £48,720,000, an increase of £332,000 over 1904. There is a marked decrease in second-class earnings, excluding season ticket holders, of £211,000, attributable in part to the abolition of this class on the Metropolitan and Metropolitan District Railways consequent on their electrification, and in part due to a reclassification of the revenue of the Liverpool Overhead Railways, where the cheaper of the two classes was formerly classed as "second" but now as "third." The total number of ordinary passengers carried was 1,199,022,000, of whom 1,110·0 millions were third-class, 52·6 millions second-class, and 36·4 millions first-class. The average receipts per ordinary passenger were, third-class 6·5d., second-class 8·8d., and first-class 23·7d. The number of season-ticket holders is reckoned on the equivalent annual tickets as individual tickets are issued for varying

* Abstracted from the "Returns of the Capital, Traffic, Receipts, and Working Expenditure of the Railway Companies of the United Kingdom for the Year 1905." (Cd 3106.) Printed by Wyman and Sons, Ltd., Fetter-lane, E.C Price 1s. 3d.

terms. These amounted to 129,893 first-class (a decrease of 896), 157,685 second-class (a decrease of 11,587), and 275,462 third-class (an increase of 31,650). The receipts per annual season ticket were, first-class £11 2s., second-class £6 10s., and third-class £4 8s.

Goods Traffic.—The traffic receipts from the carriage of minerals, merchandise, and live stock increased during 1905 by 1,012,000 to £56,412,000. The weight of minerals conveyed was 358·1 million tons, and of general merchandise 101·1 million tons. In the case of minerals, the proportionate increase in weight is approximately the same as that in receipts, but that in the case of general merchandise the rate per cent. of increase is nearly twice as great in the weight as in receipts, viz., 2·8 per cent. as against 1·5 per cent.

Train Mileage.—Although information is still lacking as to ton-mileage and passenger-mileage statistics, particulars are given which show that the mileage of passenger trains was 244·4 million as against 240·0 million miles in the preceding year. With regard to the goods traffic, the train mileage amounted to 154·8 million tons as against 155·2 million tons in 1904. The efforts made to reduce goods train mileage resulted in a decrease of 400,000 miles, following on decreases of 4,500,000 miles in 1904, and 10,000,000 miles in 1903. This result in 1905 has been achieved in the face of the increased tonnage of goods carried, amounting to 11,300,000 tons, the figures thus continuing to indicate an increase in the average load of goods trains. With regard to passenger train mileage, however, there was an increase of some 4,400,000 miles in 1905, although the total number of passengers carried was approximately the same as in 1904, the indication in this case being that the companies were placing greater facilities at the disposal of the travelling public. The receipts per passenger train mile were 47·58 pence, a decrease of 0·51 pence on the 1904 earnings, these being the lowest passenger train earnings since 1888. Goods earnings per goods train mile reached the record figure of 87·29 pence, an advance of 1·87 pence on the 1904 earnings, and an advance of 16·23 pence since 1900. This is attributable to the better loading, longer trains, and more powerful engines.

Working Expenditure.—The proportion of working expenses to gross receipts was again 62 per cent. The total working expenses of 70·06 millions sterling were actually £890,000 greater than in 1904. The expenditure on "Maintenance of Way, &c.," decreased by £10,000, as against increases of £70,000 in 1904, and £320,000 in 1903. That on "Repairs and Renewals of Carriages and Waggons" increased by £130,000 in 1905, as compared with £50,000 in 1904, whilst "Traffic Expenses" increased by £110,000, as against £120,000 in 1904. The expenditure for "Locomotive Power" (including repairs and reuewals) which showed a falling off of £820,000 in 1902, £180,000 in 1903, and £30,000 in 1904, showed a slight increase of £20,000 in 1905. Taking the above four principal heads of expenditure together, the total increase amounted to £250,000, which compares with an increase under the same heads in 1904 of £210,000. Of the remaining heads of expenditure, the increase in the "Miscellaneous" expenditure, including steam-boats, docks, &c., amounted to £350,000.

Increase in Rates and Taxes.—The total amount paid in rates and taxes in 1905 was £4,933,000, an increase of £197,000 over 1904. The increase since 1896 has been £1,784,000, or about 56 per cent. This latter item has now become of serious importance. Reckoning its cost per train mile it amounts to 2·95 pence out of the average total cost per train mile of 39·79 pence.

THE GERMAN POTASSIUM INDUSTRY.

Germany enjoys the distinction of being, so far, the only country in which potassium salts, called kali, have been discovered in very large quantities, and can be said to possess a monopoly of these valuable mineral deposits. The year 1905 was, according to the American Consul at Brunswick, the most prosperous in the history of the potassium mining industry. The feeling of security produced by the renewal of the potassium syndicate in 1904, for five years, and the continuous increase in the sales of the old mines, and their immense profits, have led to the organisation of a great number of new mining companies. Kali is exported from Germany in large quantities, and is used principally for fertilising purposes in the cultivation of cotton, tobacco, sweet potatoes, oranges, and other fruits and crops. The amount of kali, or potassium salts, produced by the mines, amounted in the year 1879 to 661,700 tons. In 1904, the amount produced had reached 3,939,518 tons. The principal part of this increase consists of so-called manure salts for agricultural purposes. The large export to other countries, and the exhaustion of land surfaces by active cultivation at home, increase the demand for these salts, and show that they are becoming a necessity. Three States are represented in the potassium syndicate—namely, the Kingdom of Prussia, and the Duchies of Brunswick and Anhalt. Besides it present holdings in the syndicate, the Prussian State Treasury for Mines, has bought for £1,500,000, the valuable Hercynia mine at Wernigerode. The object is to strengthen Prussia in the syndicate, and to give it a predominating influence in the present state of the industry. It is said that the purchase of other mines is contemplated by the same Government. Brunswick is represented by the Asse Mine, which was leased to the syndicate for twenty-five years, from 1879, at the annual rental of £10,000. It is provided in the contract that if the rental falls below that amount for three successive years the lease can be cancelled by the State. On the other hand, the State is prohibited by the contract from granting mining claims to outside parties during its continuance, or

exercising the right of opening mines itself during that period. The year 1905 has been called "founding year" in the potassium mining industry. The fever of organising new companies during the year reached such a stage as to threaten the stability of the syndicate, and to cause serious apprehensions as to the future prices for the products of the mines. In order to restrain this speculative activity, a law was passed by the Prussian legislature limiting the granting of mining claims for coal and kali to two years. On account of this measure speculators transferred their sphere of activity to the State of Hanover, where mining claims are not subject to this law. The result is that scarcely a spot of ground remains open which is not covered by a mining contract for potassium. The number of companies organised during the year is said to have reached considerably over 50. The geological formation in which the mining operations are carried on is sand interspersed with strata of water-bearing gravel. This formation makes mining extremely hazardous owing to exposures to caving and flooding. Under the Prussian law the dimensions of a maximum claim for which mining rights may be granted is about 500 acres. A potassium mine before it becomes profitable usually costs from £250,000 to £300,000. In searching for new sources of revenue the proposition has lately been brought before the tax committee of the Reichstag to levy an export duty on potassium salts. The proposition has been supported by the Landwirthschaft, or agricultural party, as a means of protecting German agriculture from foreign competition, while it has been opposed by the potassium syndicate on the ground that the salts are little used in the cultivation of foreign wheat, the chief article of competition, and that the tax would be difficult of collection and highly injurious to an industry engaged in exporting a valuable article of commerce. The committtee has recently rejected the proposition and removed a disturbing factor from the industry. From time to time reports are published of the purchases of large interests in potassium mines by English and American capitalists. There is no doubt that such purchases have been made, but it would be difficult to ascertain their extent. It is generally understood that the majority of the shares of the mine "Einigkeit," one of the less important members of the syndicate, is controlled by American capital. At the beginning of the present year it was stated on good authority that a majority of the shares of the mining property, "Solling," had been acquired by English investors, and that previous to this acquisition large purchases had been made by English capitalists in the mining companies, Wallensen, Thuisten, and Duingen.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in October :—

New Charts.—3598—The World :—Lines of equal magnetic dip 1907. 3603—The World :—Mean lines of equal horizontal force 1907. 1406—North sea :—Dover and Calais to Orfordness and Schevenigen. 3596—South America, Magellan strait :—Puerto Zenteno (Pecket harbour); Canal Tortuoso; Laguna Baja. 40—India, west coast :—Karáchi harbour (Kurrachee). 3581—India, east coast :—Approaches to Pámbam pass. 3597—Gaspar strait :—Approaches to Tanjong Pandan. 3037—Korea, Port Lazaret and Yung hing bay; on Shan Tin (Gensan bay). 2387—Japan :—Io jima to Madara jima, including Hirado shima. 3591—Japan :—Iburi wan or Uchiura wan (Volcano bay).

New Plans and Plans added.—160—Plans on the west coast of Italy—New plan :—Mouth of the Tiber. 2761—Sumatra, west coast; Chingkuk bay to the strait of Sunda. New plan :—Silabulabu anchorage. 912—Anchorages in islands off the north-west part of New Guinea. New plan :—Labuha road. 2193—Celebes; sketch plan of anchorages between Mindanao and Celebes. Plan added :—Esang bay. 1592—China, east coast; Yung river and approaches. Plan added :—Ning po anchorage. 3375—Plans on the south coast of Japan. Plans added :—Mimitsu anchorage; Oryuzako anchorage. 2467—Plans of anchorages on the north coast of New Guinea. New plan :—Matterer bay.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners :—30—England, south coast :—Plymouth sound and the Hamoaze. 1951—England, west coast :—Liverpool bay. 3021—England, east coast :—River Medway between Pinup and Chatham reaches. 3177—South Polar chart, showing tracks of vessels and discoveries. 2840—British Columbia :—Haro strait and Middle channel. 1697—Africa, west coast :—Garraway point to Growa point. 1003—Africa, east coast :—Pungue river; Beira harbour. 8c—Red Sea. Sheet III. 81—Red Sea :—Merser Durúr to Trinkitat, showing the approaches to Sawákin. 136—Bay of Bengal, river Húgli :—Sangor point to Calcutta. 1761—China, east coast :—Ockseu islands to Tung Yung.

These charts are issued by Mr. J. D. Potter, 145, Minories.

COTTON GROWING IN THE WEST INDIES.

Sir Alfred Jones, K.C.M.G., President of the British Cotton Growing Association, has offered two gold medals for competition amongst Sea Island cotton growers in the West Indies, that is one for growers of ten acres and over, and one for growers of less than ten acres. These medals are to be awarded on the crop results for 1906. Sir Daniel Morris reports that this year the total crop of Sea

Island cotton in the West Indies is of the estimated value of £140,000, and it must be remembered that the industry is not yet five years old.

In connection with this offer of medals, it is interesting to note that the Society of Arts attempted, soon after its institution, to encourage, by means of the offer of medals, the growth of agriculture in the Colonies. In 1768, a gold medal was offered "For the best specimen, not less than 10 lb., of cotton produced in the British dominions in America, equal to the fine Brazilian cotton to be produced, with certificates of the place of growth, on or before the first Tuesday in January, 1770."

This offer was annually repeated until 1777. In 1778, the gold medal was given to Mr. Andrew Bennet, of Tobago, for the best specimen of West India cotton. Mr. Bennet sent an account of his experiments and observations, which is printed in the *Transactions*, vol. 1, p. 254.

THE LIBRARY.

The following books have been presented to the Library since the last announcement:—

Australia, Year Book of, 1906.—Presented by the Agent-General for New South Wales.

Banaji, Khoshru N.—The Simplex Shorthand in Theory and Practice. Bombay: "Times" Press. 1906. Presented by the Author.

Bayley, R. Child.—The Complete Photographer. London: Methuen and Co. 1906. Presented by the Publishers.

Beadle, Clayton.—Chapters on Papermaking. Vol. II. London: H. H. G. Grattan. 1906. Presented by the Author.

British Rainfall, 1905.—Compiled by H. R. Mill, D.Sc., LL.D. London: E. Stanford. 1906. Presented by the Compiler.

Bushell, Stephen W., C.M.G., M.D.—Chinese Art. Vol. II. London, 1906. Presented by the Board of Education.

Caven, R. M., D.Sc., and G. D. Lander, D.Sc.—Systematic Inorganic Chemistry. London: Blackie and Son, Ltd. 1906. Presented by the Publishers.

Christie, Mrs. A. H.—Embroidery and Tapestry Weaving. London: John Hogg. 1906. Presented by the Publisher.

Crookes, Sir William, D.Sc., F.R.S.—Select Methods of Chemical Analysis, chiefly Inorganic. Fourth Edition. London: Longmans, Green and Co. 1905. Presented by the Publishers.

Cross, C. F., and E. J. Bevan.—Researches on Cellulose. Vol. II. 1900-1905. London: Longmans, Green and Co. 1906. Presented by the Publishers.

Dowson, J. Emerson, and A. T. Larter, B.Sc.—Producer Gas. London: Longmans, Green and Co. 1906. Presented by the Publishers.

Elliot, G. F. Scott, M.A., B.Sc.—A First Course in Practical Botany. London: Blackie and Son, Ltd. 1906. Presented by the Publishers.

Findlay, Alex., M.A., D.Sc.—Physical Chemistry. London: Longmans, Green and Co. 1905. Presented by the Publishers.

Fleming, J. A., M.A., F.R.S.—The Principles of Electric Wave Telegraphy. London: Longmans, Green and Co. 1906. Presented by the Author.

Greece, The Description of, by Pausanias. Translated from the Greek, by Thomas Taylor. 3 vols.—London. 1824. Presented by Sir George Birdwood, K.C.I.E., C.S.I.

Holmes, Sir George C. V., K.C.V.O., C.B.—Ancient and Modern Ships. Two vols. London: 1906. Presented by the Board of Education.

Johnston, Edward.—Writing and Illuminating and Lettering. London: John Hogg. 1906. Presented by the Publisher.

London County Council.—Report, 1904-5. London Statistics, 1905-6. Presented by the London County Council.

Mendeléeff, D.—The Principles of Chemistry. Translated from the Russian (7th Edition) by G. Kamensky, and Edited by Thomas H. Pope. 3rd English Edition. Two vols. London: Longmans, Green and Co. 1905. Presented by the Publishers.

Morton, Arthur E.—Modern Typewriting and Manual of Office Procedure. 4th Edition. London: Smith Premier Typewriter Company. Presented by the Publishers.

New South Wales Statistical Register for 1904 and previous years. Official Year Book, 1904-5.—Sydney: W. A. Gullick. 1906. Presented by the Agent-General for New South Wales.

New Zealand Official Year Book, 1906. Prepared by E. J. Von Dadelszen. Wellington: John Mackay. 1906. Presented by the Registrar-General.

Radcliffe, Lionel G. and Frank S. Sinnatt.—A Systematic Course of Practical Organic Chemistry. London: Longmans, Green and Co. 1905. Presented by the Publishers.

Ranade, Mahadev Govind, C.I.E.—Essays on Indian Economics. 2nd Edition. Madras: Natesan and Co. 1906. Presented by the Publishers.

Schlich, W., Ph.D., C.I.E.—Manual of Forestry. Vol. I.—Forest Policy in the British Empire. 3rd Edition. London: Bradbury, Agnew and Co. Ltd. 1906. Presented by the Publishers.

Thorpe, T. E., F.R.S.—Joseph Priestley. London: J. M. Dent and Co. 1906. Presented by the Publishers.

Welch, G. E., B.Sc.—Chemistry Lecture Notes. London: Blackie and Son, Ltd. 1905. Presented by the Publishers.

Westall, George.—Rateable Machinery. London: P. Allen and Co. 1905. Presented by the Author.

HOME INDUSTRIES.

The Channel Traffic.—This is not the place to discuss the political considerations that must weigh with those who have to decide whether there is to be a tunnel between England and France, but it may not be out of place to note its probable effect upon British imports into France. In the opinion of many experts they would be greatly helped by through land communication. And this opinion seems to hold in France as here. "Imagine," said a French manufacturer quoted by the *Pall Mall Magazine*, "a train steaming direct from Manchester into the Gare du Nord. It could bring any quantity of cotton and woollen fabrics from the north of England, which could be sold at a price inferior to our own, or at least not superior. The only reason why a larger trade is not at present done with England is because of the lapse of time between the giving of an order and its completion. Roughly, you may say, it takes a week to get any given article from England; but if the goods came by train, with only two handlings, this time could be reduced to a third, or even less." Assuming this forecast to be sound, and accepted by British manufacturers, it does not of course, necessarily follow that the tunnel ought to be cut. The security of the kingdom must be the first consideration; but probably what may be called the trade argument will figure largely in coming discussions.

Shipping in 1906.—The past year saw the largest addition to the British mercantile marine ever made in twelve months. The effective tonnage was increased by about 1,000,000 tons of dead weight-carrying capacity, the total addition to the register being 1,550,000 tons. The merchant steamers turned out of the shipyards represent 1,800,000 tons gross, an addition of 12½ per cent. upon the production of 1905. The way in which ship builders were able to induce ship managers to order tonnage was remarkable. Although the majority of ship managers were able to do no more than cover the depreciation of the steamers entrusted to their care, orders for larger vessels were placed whenever a steamer was sold or lost, or the freight markets showed any signs of a profitable level approaching. This readiness to build is generally assumed to be due to the prosperous condition of the industry, but Messrs. Angier Brothers, in their steam shipping report for 1906, suggest that it is rather owing to the fact that other outlets for capital are becoming more circumscribed, and that the over-sea carrying is the one trade which it has been impossible to surround with a tariff wall. Be that as it may, the Americans and French seem content to let the British do their ocean carrying if they can secure the profitable work of growing and manufacturing the cargo. The American mercantile marine grows only slowly, notwithstanding subsidies, and the French marine is less than one-tenth of the British, though heavy subventions are paid. The German fleet is the second largest in ocean ships with 3,810,000 tons, but of 2,081,000 net register tons of steamers, 1,081,568 tons are owned by five great lines, which, besides receiving large payments for carrying the mails, are preferentially treated by the Government railways in regard to both goods and passengers.

The Iron and Steel Trades.—Whilst here and there some branch of the iron and steel trades—as for example, the boiler-makers—complain that it has done less well than others, collectively the trade has seldom done better than in 1906. To quote from the annual record of the situation made by Messrs. Billing and Lowe, "the general result of 1906 may be taken all round as very satisfactory, and those countries whose staple industries are the production of iron and steel, and the cultivation of allied trades, have had a time of exceptional prosperity." The output of pig iron in the year is put at 11,000,000 tons an excess of 2,600,000 over the figures of 1905. Prices have risen some 20 per cent., Middlesboro' No. 3 from 53s. 3d. to 63s. 6d. and West Coast hematite from 71s. 6d. to 80s., but the prices of manufactured iron and steel remained practically unchanged. Not only was the past year an exceptionally good one for most branches of the trade, there is reasonable ground for the belief that 1907 will also be a very good year. Many firms are practically assured of big returns, owing to the extent of their engagements ahead, and as these engagements are mostly based on the high values of last year, profits are likely to be larger than in 1906 seeing that part of the work of last year was done at contract prices fixed before the rise in the value of raw materials had taken place.

Railway Dividends.—The past half-year has on the whole been a good one for the railway companies. Higher receipts, as compared with the corresponding six months of 1905, were general, and in most cases improved dividends may be anticipated, the exceptions being the Great Central, South Western, and London Brighton and South Coast, due in the first case to new capital charges, and extra expenses due to the opening of the new Great Central and Great Western joint lines, and the new agreement with the Metropolitan; in the second to the Salisbury disaster, and in the third to the charges on new capital. Naturally the lines associated with the great industrial centres have benefited most, the North Eastern leading the way with an increase in gross receipts of something like £300,000. Speaking generally, and excluding London local railways, the ncrease in receipts has been substantial. On the other hand expenses have absorbed much of the increased revenue. Materials and labour have cost more, rates and taxes continue to advance, though less rapidly, thanks to successful appeals to the courts, and the South Western and Great Northern Railways have to face heavy "compensation." Still the extra net profit in most cases should be appreciable. It is noteworthy that the railways more especially dependent upon the pleasure travel of

Londoners have done less well, and the ordinary stocks of London local railways are quoted at a discount—often a heavy one. The "tubes" are not financially successful. They have done much to relieve congestion in the streets; but they do not, and are not likely to, give an adequate return upon the capital employed. The Central London has done the best, but it has never paid more than 4 per cent. on its ordinary stock. Nor has the electrification of the Metropolitan and District Railway improved its financial position. Capital charges have been seriously increased without any compensating improvement in the revenue. The prospectus issued by the Great Northern and City (in 1898) estimated net revenue at £81,500, and a second prospectus issued in 1904, immediately before the line was opened, put it at £79,680, but the reality has, so far, fallen far short, the actual results for the year to June 30th last, showing a net revenue of only £46,722. The London railways have to reckon with exceptional difficulties. Rates are unusually heavy—the Central London pays £32,000 a year in rates and taxes, equal to 1 per cent. per annum on the ordinary stock—the competition of road vehicles having free use of the roads, and paying nothing to the cost of widening, is very severe, and whilst the capitalisation per mile of line is unusually high, fares are exceptionally low.

Banking Results.—With a margin of 2 per cent., between the Bank rate and the rates paid on deposits the banks are doing well just now, and although the dividends declared for the six months just ended are not larger than those for the corresponding period of 1905 there has been increase in the profits earned. The London and Westminster Bank has increased its profits for the six months by some £41,000; the London Joint Stock Bank by over £40,000; the London City and Midland by £21,000; William Deacon's Bank being the only one which has substantially increased its dividend for the whole year, as from 13¾ per cent. to 15 per cent. In giving the figures of the clearings for 1906, the secretary of the Bankers' Clearing House says that for six successive years the yearly totals of the paid clearings have exceeded all previous totals, "a sequence only equalled in length by the years 1868 to 1873, in the last year of which the total was less than half the year's total for 1905." Yet the increase for last year was £423,399,000, or 3·4 per cent., as against an increase in the previous year of £1,723,738,000, or 16·3 per cent.

The Wool Trade.—As in so many other cases, the past year was very favourable for the producers of the raw material, but if 1906 was pre-eminently a year for the growers, makers have been very active. The rise in the price of wool in recent years has been remarkable. Wool that five years ago could be bought for 4d. per lb. cannot now be got at less than 14d., and it looks as if the highest point has not been reached. It was supposed that the increasing supplies from Australia would lead to a fall in prices, and many Bradford importers sold forward at as much as a penny less than current rates, but the demand kept pace with the supplies, and to-day stocks are pretty well exhausted. And all descriptions of home-grown and colonial wool have shared in the demand, cross-bred wools, which were thought certain to fall away from their high level, having touched a higher point than for a generation. Bradford is busier than at any time of the year, which is saying much, and expert opinion points to a continuance of the good times.

The Rubber Trade.—It is a little surprising that, having regard to the rapid growth of the cycle and motor industries, with their rubber requirements, the imports of rubber last year were a trifle less than in 1905—21,269 tons as against 21,700 tons—and that the highest quotations have not been quite maintained. Fine grades of Para, Bolivian, and Peruvian show a decline of 2d. on the year. Opinions differ as to the future. The world's supply increased from, roughly, 60,000 tons in 1905 to 65,000 tons last year, but all was absorbed. Increased supply has met rising consumption but that is all, and it is difficult to believe that it will do more in the immediate future. Additions are constantly being made to the area under cultivation. In Ceylon, Malaya, Malacca, and Sumatra, Java, Borneo, Nicaragua, Honduras, Brazil, the West Indies, considerable areas have been planted with rubber recently, but it must be some years before their produce materially affects the market, and meantime it will be becoming increasingly difficult to get uncultivated rubber. But that ultimately, and before very many years have passed, supply will get ahead of demand is probable, notwithstanding that the supplies from some sources are steadily decreasing. There is little possibility of new rubber-producing areas being discovered that would seriously affect the market, but the cultivated area is certain to rapidly extend. Rubber can be grown in nearly all tropical lands, and at anything like present prices it can be made to yield a large profit. It is not difficult to grow, the drawback, from the point of view of the ordinary settler being the time that elapses before a plantation comes into profitable bearing. But after all it is not much, if any, longer than the time taken by a cocoa plantation to mature, and once established, it will return not only a handsome profit upon outlay, but one assured for many years. It would seem to follow that the area under cultivated rubber must continue rapidly to increase whilst prices remain upon anything like their present level.

GENERAL NOTES.

British Trade with Switzerland.—Mr. J. C. Milligan, British Commercial Agent in Switzerland, is of the opinion, as stated in his Annual Report on the Trade of Switzerland (Cd. 2682), that the United

Kingdom might largely increase her exports to Switzerland if British manufacturers went the right way to work. It is pointed out that while Switzerland sent us, in the year under review, her manufactured goods to the value of £6,953,000, we were only able to send her our finished goods to the amount of £2,146,000, so that there was a difference of £4,800,000 in favour of Swiss commerce between the two countries. It is true that the British exports to Switserland of cotton yarns and textiles reached last year £1,242,000, but the light returns we can show in the exports of all other finished goods is £904,000 out of a total of more than £17,000,000. Mr. Milligan is confident that a larger trade could be done by British exporters if they would conform to the custom of the country and be willing to sell to both the large and small retailers. And he seems to think that the United Kingdom is insufficiently represented by commercial travellers. In 1905 no fewer than 4,838 German commercial travellers visited Switzerland, the German percentage of the total imports to Switzerland being 53·2 per cent. On the other hand, there were only 53 travellers from the United Kingdom, and the percentage of imports from the United Kingdom was only 11.

CUBA.—The growth of population in Cuba since the war with Spain is remarkable. In his report on the trade of the island just issued, Mr. Vice-Consul Griffiths gives the figures. According to the census of 1899, the population in the year numbered 1,572,797; in January of the present year it had increased to 1,878,951; the death-rate being only 14·38 per 1,000 inhabitants; but in Havana 21·20. Immigration shows large and constant increase in the same period. In 1900 the immigrants numbered 19,110; in 1905, 54,219. Railway construction is proceeding apace, and the Vice-Consul reports that there is a good opening in Cuba for the supply of cheap, serviceable standard narrow gauge cars for carrying sugar-cane in bulk, the orders for the majority of these at present going to the United States. There is also a demand for ox or horse-cart weighbridges, which are used for the purpose of weighing the cane before delivering to the railway companies. The United Kingdom maintains her supremacy in the shipping going to Cuba, but 46¾ per cent. of the imports of 1905 came from the United States; the United Kingdom being second with 17½ per cent. The total commerce of the island amounted to £41,025,000 as against £33,208,000 in 1904, an increase only of 23½ per cent.; imports and exports having gained in practically the same ratio.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

JANUARY 16, 1907.—Adjourned Discussion on Mr. J. W. GORDON's paper, on "Patent-law Reform." SIR WILLIAM PREECE, K.C.B., F.R.S., will preside.

JANUARY 23.—"The Isthmus of Panama." By PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

JANUARY 30.— "Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 24.—"The Bhils of Western India." By CAPTAIN E. BARNES, Indian Political Department. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

FEBRUARY 14.—"The Practical Side of Famine in India." By SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces.

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 15.—"The Progress of the Uganda Protectorate." By GEORGE WILSON, C.B., Deputy Commissioner Uganda Protectorate. Colonel SIR FREDERICK D. LUGARD, K.C.M.G., C.B., D.S.O., will preside.

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

FEBRUARY 19.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

LECTURE I.—JANUARY 28.—*Alluvial Gold Mining.*—Small scale methods and manual appliances—Hydraulic sluicing — Gold dredges; chief types; ground to which suitable; costs—The deep leads of Australia; their nature; distribution; methods of discovery and mining.

LECTURE II.—FEBRUARY 4.—*Lode Mining.*—The term "reef" used both for ore and "country" rock—The chief types of gold-bearing lodes—The importance of ore genesis in reference to mine development—The chief gold fields of the world and their structures—The Rand and its banket.

LECTURE III.—FEBRUARY 11.—*Gold Production.*—The crushing of the ore; the stamp mill—The extraction of gold by amalgamation; smelting; chlorination and cyanidation—Reforms in consequence of the tube mill and the filter press—The depth of ores; surface and secondary enrichment—Mining costs and gold mining organization.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S, "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 14...Surveyors, 12, Great George-street, S.W., 8 p.m Discussion on Paper by Mr. E. H. Blake, "Some Notes on Sanitary Law."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. J. Masterman, "Some Recent Developments in the British Constitution."

TUESDAY, JAN. 15. SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. George Wilson, "The Progress of the Uganda Protectorate."

Asiatic, 22, Albemarle-st., W., 4 p.m. Dr. Grierson, "Modern Hinduism and its Debt to the Nestorians."

Hellenic Studies, Society of Antiquaries, Burlington-house, W., 5 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Percy Gardner, "The Sculpture of Ægina in relation to Recent Discovery." (Lecture I.)

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. Mr. E. E. Fournier D'Albe, "The Application of the Electron Theory to Electrolysis."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Francis Fox's paper, "The Simplon Tunnel."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. E. B. Sargant, "Federal Tendencies in Education."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, JAN. 16..SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Adjourned Discussion on Mr. J. W. Gordon's paper, on "Patent-law Reform."

Meteorological, 25, Great George-street, S.W., 7½ p.m. (Annual Meeting.) Address by Mr. Richard Bentley (President), "Weather in War Time."

Microscopical, 20, Hanover-square, W., 8 p.m. (Annual Meeting.) 1. Address by the President, "The Flowering Plants of the Mesozoic Age." 2. Exhibition by Mr. Rousselet of mounted specimens of fresh-water polyzoa.

United Service Institution, Whitehall, S.W., 3 p.m. Major R. A. Johnson, "The Swiss Militia System."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, JAN. 17..Antiquaries, Burlington-house, W., 8½ p.m.

Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. W. Botting Hemsley, "*Platanthera chlorantha*, Custor, var, *tricalcarata*." 2. Paper by the late Mr. C. B. Clarke, "Acanthaceæ of insular Malaya." 3. The Rev. T. R. R. Stebbing, "A Freshwater Isopod from Calcutta."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. A. W. Stewart, "The Relation between Absorption Spectra and Optical Rotatory Power. Part I. The Effect of Unsaturation and Stereo-isomerism." 2. Mr. F. S. Kipping, "Organic Derivatives of Silicon. Part II. The Synthesis of Di-ethyl Propyl Benzyl Silicol, its Sulphonation, and the Resolution of the Sulphonic Derivatives into Optically Active Compounds." 3. Messrs. J. J. T. Hewitt and T. F. Winmill, "The Association of Phenols in the Liquid Condition." 4. Mr. J. T. Hewitt, "A New Mercuric Oxychloride." 5. Messrs. S. Smiles and T. P. Hilditch, "Aromatic Selenonium Bases." 6. Mr. A. G. Green, "The Relation of Colour and Fluorescence to Constitution." 7. Mr. E. Divers, "The Constitution of Silver Nitrite; a Correction." 8. Messrs. F. D. Law and F. M. Perkin, "Preparation of Chromyl Chloride." 9. Messrs. A. T. de Noulpied and A. Rule, "Tetraketopiperazine."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. Harrison Townsend, "The Art of Pictorial Mosaic."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. N. Shaw, "Recent Advances in the Exploration of the Atmosphere." (Lecture I.)

Historical, Clifford's-inn Hall, Fleet-street, E.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, JAN. 18...Royal Institution, Albemarle-street, W., 9 p.m. Sir Andrew Noble, "Fifty Years of Explosives."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m, Paper on "Stencilling."

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Adjourned discussion on "Lighting of Railway Premises: Indoor and Outdoor." 2. Pro- ds, fessor H. C. H. Carpenter and Mr. C. A. Edwar ttee: Eighth Report to the Alloys Research Commi on and "The Properties of the Alloys of Aluminiu C Copper." and eet, W.,

SATURDAY, JAN. 19..Royal Institute, Albemarle-st ort oe Lates 3 p.m. Sir Alexander Mackenzie, "Th Unite Phases of Music." (Lecture I.)

Journal of the Society of Arts.

No. 2,826. VOL. LV.

FRIDAY, JANUARY 18, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 23, 8 p.m. (Ordinary Meeting.) PHILLIPPE BUNAU-VARILLA, "The Panama Canal—The 'Lock Canal' type and the 'Straits of Panama' type."

THURSDAY, JANUARY 24, 4.30 p.m. CAPTAIN E. BARNES, "The Bhils of Western India."

Further details of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

Tuesday afternoon, January 15; COLONEL SIR FREDERICK D. LUGARD, K.C.M.G., C.B., in the chair. The paper read was "The Progress of the Uganda Protectorate," by GEORGE WILSON, C.B., Deputy-Commissioner Uganda Protectorate.

The paper and report of the discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ARTIFICIAL FERTILISERS: THEIR NATURE AND FUNCTION.

BY A. D. HALL, M.A.,
Director of the Rothamsted Experimental Station, Lawes Agricultural Trust.

Lecture IV.—Delivered December 10th, 1906.

Before passing on to the phosphatic manures, it is necessary to consider how far each of the three substances—nitrogen, phosphoric acid, and potash—possesses a specific effect that shows itself in the plant whenever there is either an excess or defect of the particular constituent in the soil. To answer this question properly, we should require to know what is the physiological function of each of these constituents of the plant's food, and though we are still far from any fullness of knowledge, certain general conclusions may be drawn both from field experiments and from the experience of the farm. In the first place, nitrogen is mainly concerned with the vegetative growth of the plant, with the formation of leaf and stem which are the necessary preliminaries to complete development. A deficiency of nitrogen results in a stunted general growth, in which the grain or seed bears a high proportion to the whole weight of the crop; the plant on analysis, however, shows no marked lack of nitrogen as compared with the other constituents. These other bodies, phosphoric acid, potash, &c., in whatever excess they may be present in the soil, are only taken up by the plant as it can use them, *i.e.*, in quantities proportionate to the growth, which in its turn is proportionate to the nitrogen supply. As the amount of available nitrogen is increased the development of leaf and shoot increases, their green colour deepens, and maturity tends to become more and more deferred, so that a crop grown on land over-rich in nitrogen, always tends to be late and badly ripened and to show a profusion of leaf, characters which, in the case of a grain crop, often result in lodging before harvest.

But the fact that the primary growth of the plant is up to certain limits almost proportional to the supply of nitrogen, so that an application of nitrogenous manure has a quickly visible effect, not only makes it the leading constituent of a fertiliser, but is apt to give it a fictitious importance in the farmer's eyes. The following Table shows how with increasing nitrogen it is the straw that benefits more than the grain :—

TABLE XIX.—INCREASE PER CENT. FOR EACH ADDITION OF NITROGEN.

	Wheat Grain.	Wheat Straw.
43 lb. N.	56·3	63·3
86 ,, ,, ...	46·4	66·3
129 ,, ,, ...	10·4	28·0
172 ,, ,, ...	2·7	23·5

As the nitrogen comes to be in excess, various secondary effects manifest themselves, chiefly due to over-development of the vegetative parts of the plant. Flowers tend to double and proliferate, organs like the pales and glumes of barley grow extra stout, and the grain assumes a coarse appearance; at the same time the tissues of the plant are soft and weak, so that it easily falls a prey to fungoid attacks. This latter effect is very palpable on the Rothamsted mangel plots, some of which receive relatively an excessively high amount of nitrogenous manure. On these plots, and only on them, there annually occurs a leaf-spot disease—*Uromyces betae*—which towards the end of the season almost wholly destroys the leaves of the mangels on the high nitrogen plots, whereas it is not to be seen elsewhere. It has been ascertained that the epidermis and other tissues of the leaf are actually thinner in the cell wall when they have been grown with an excess of nitrogen, but this is probably not the main cause of the incidence of the fungoid disease, which is more likely to be due to the formation of a cell-sap more congenial to the fungus. Similarly, among cereals like wheat rust is always most prevalent on the plots receiving the greatest amounts of nitrogen, or again in seasons or climates giving rise to an exceptionally high temperature of the soil in early spring, so that there is for a time an over-rapid production of nitrates for the plant. For example, in countries where a rainless or a too severe winter compels the sowing of spring wheat late in the season, followed by high temperatures with plenty of moisture, the first growth is extremely rapid, and rust is always very prevalent; over the greater part of South Africa wheat and barley cannot be grown for this reason.

Just as nitrogen delays maturity by promoting growth, phosphoric acid has an opposite effect; it is in some way closely bound up with grain formation, being always found in greater proportions in the reproductive parts of the plant than elsewhere. This ripening action is very clearly seen in the Rothamsted experiments on barley; the plots without phosphoric acid being as a rule about a week behind those which receive this fertiliser. Naturally, such an effect of phosphoric acid is particularly seen in a wet year when the crop is late to harvest. The following Table will illustrate the point: it gives the yield and other particulars of one series of the Rothamsted barley plots in 1893, a specially dry season, and in 1894 which was almost equally wet.

TABLE XX.

	Grain, bushels.		Grains to 100 Straw.		N Per Cent. in Grain.	
	1893.	1894.	1893.	1894.	1893.	1894.
Ammonium salts alone	11·6	10·4	85·3	67·5	2·19	1·65
Ammonium salts and superphosphate	18·1	34·9	101·0	77·0	2·13	1·60
Ammonium salts and potash	16·8	17·8	85·9	73·8	2·17	1·61
Ammonium salts, super, and potash..	30·8	41·4	102·2	77·7	2·08	1·44

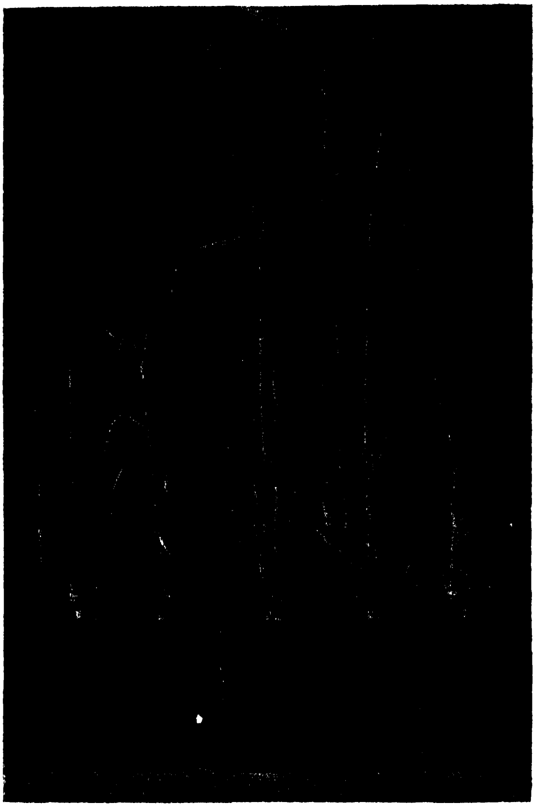
The phosphoric acid increases the proportion of grain to straw, and decreases the nitrogen content of the grain, and it will be noticed that this latter effect is more marked in the wet season of 1894. Even in the yield itself the phosphoric acid had the greater effect in the wet season.

The action of phosphoric acid on the plant is not confined to its ripening effect; it stimulates the early development of the young seedling to a remarkable extent. Farmers are well acquainted with the good start that any crop gets when manured with superphosphate; indeed it is often used merely to secure a better plant, though with little expectation of otherwise increasing the yield. More than sixty years ago this had been noticed by the late Sir John Lawes; and in one of his earliest papers on "Turnip Culture," in 1847, he writes: "Whether or not superphosphate of lime owes much of its effect to its chemical actions in the soil, it is certainly true that it causes a much enhanced development of the underground collective appa-

ratus of the plant, especially of lateral and fibrous root."

In this statement he was vigorously attacked by Liebig, but some experiments, which are still in progress, show that it was the result of sound observation, and that in some way or other phosphoric acid does stimulate the root development of the young plant. The photograph (Fig. 2) shows a series of water cultures of barley growing in solutions which are alike as far as regards the nitrogen, potash magnesia, lime, &c., but which differ as regards phosphoric acid, being respectively 0, 1-20,000th, 1-8,000th, 1-2,000th, and 1-1,000th normal solutions of that constituent. The root development, which is practically nil in the absence of phosphoric acid, increases with each addition up to about 1-2,000th normal strength. Similar water cultures, in which nitrogen or potash is omitted (see Fig. 1, p. 135), while they show equally feeble development of the plant as a whole, yet give rise to a comparatively extensive root development.

FIG. 2.



1 2 3 4 5

EFFECT OF PHOSPHORIC ACID UPON ROOT DEVELOPMENT OF BARLEY IN WATER CULTURES.

1. Solution contains no Phosphoric Acid.
2. ,, = 1-20,000 normal Phosphoric Acid.
3. ,, = 1-8,000 ,, ,, ,,
4. ,, = 1-2,000 ,, ,, ,,
5. ,, = 1-1,000 ,, ,, ,,

Other constituents of the solution alike in all cases.

To what extent this stimulus to root growth is brought about by other sources of phosphoric acid and under diverse conditions of soil, has not yet been worked out, but there can be little doubt but that it explains why a phos-

phatic manuring has such a valuable effect in establishing the plant, even if the gross yield is not ultimately much enhanced.

It may also go to explain the extraordinary results of quite small dressings of phosphoric acid upon soils in Southern Australia, where a manuring with half a hundred-weight per acre or even less of superphosphate has been found sometimes to double the yield of cereals. On analysis the soils are not rich, but they show no such signal deficiency in phosphoric acid as would account for the action of the manure; it seems much more likely that in a semi-arid country where the whole success of the crop depends on the roots getting quickly down to the cooler and moister subsoil, the stimulating action of the phosphoric acid upon the young roots becomes of the greatest value. In this connection it may be noted that tne two crops which most respond to phosphatic manuring, turnips and barley, are both possessed of shallow roots, confined to a comparatively limited layer of soil; whereas, under ordinary farming conditions, wheat responds very little to phosphoric acid, and mangels hardly at all, both being deep-rooted plants.

It has sometimes been surmised that phosphoric acid is associated with the assimilation of nitrogen by the plant, and particularly with its migration from the stem or roots into the seed, the opinion being probably founded on the fact that the nucleo-proteids, so characteristic of the reproductive parts of plants, contain phosphorus. This opinion is not, however, borne out by the examination of a large number of analyses of barley grain from the Rothamsted plots; when phosphoric acid is deficient, the intake of nitrogen is not proportionally reduced; in fact, the grain grown on the plots not receiving phosphoric acid, is the richest in nitrogen.

The phosphatic manures are practically all compounds of phosphoric acid with lime, and, as is well known, four distinct combinations exist and are found in commerce. Only one, the di-hydrogen calcium phosphate, the characteristic constituent of superphosphate, is to any degree soluble in water; the others give rise to extremely dilute solutions of phosphoric acid, too dilute, as has been shown by experiment, to nourish a plant properly with however large a volume of the solution it may be in contact. Yet insoluble as di, tri, and tetra basic phosphate of lime are, when they are sufficiently finely divided, and well incorporated with the soil so as to be in contact with the roots, they are all effective in supplying the plant with phosphoric acid. An experiment of Kossowitsch's illustrates this point. He had prepared two pots of sand, with which a certain amount of insoluble phosphate was incorporated, and a third pot containing sand alone. In one of the pots containing phosphate certain plants were sown, which were also introduced into the pot of pure sand. But while the former pot was watered with pure water, the latter pot of sand was kept fed with a continuous trickle of water that had flowed through the second sand and phosphate pot without vegetation. Thus, in one case, the roots of the plant were in contact with the ground phosphate, in the other only with the solution arising from it. Of course, both sets of plants were equally furnished with nitrogen, potash, &c., but it was found that only those whose roots were in the same pot with the phosphate made a satisfactory growth; in the other pot the plants were phosphoric acid starved.

This experiment shows that the roots themselves do something towards the solution of the insoluble phosphates, a fact also seen in Czapek's extension of Sachs' original experiment, in which a slab of smooth phosphate placed in contact with the roots of a growing plant, is found after a time to be covered with etched figures of the roots. The view, however, that the solution is effected by the excretion of the acid sap, known to be contained in the roots, is not supported by any evidence demonstrating that such acid can ever get outside the root and into contact with the particles of phosphate; it is the carbon dioxide which the roots are always excreting that brings about the solution of the phosphate. At the point it leaves the root it momentarily forms a concentrated solution possessed of considerable solvent power for phosphates and carbonates.

Since only one of the commercial phosphates is freely soluble in water, yet all of them have to enter into solution before they can be utilised by the plant, the question of their relative availability is not easy to settle, and a variety of solvents have been proposed for its determination in the laboratory. In Germany, for example, basic slag is usually valued, not on the total amount of phosphoric acid it contains, but on the amount that is soluble in a strong ammoniacal solution of ammonium citrate, the idea being that this re-agent discriminates between the tri-calcium phosphate, which is insoluble, and the di and tetra calcium phosphates, which will dissolve

in the medium. Instead of the ammonium citrate, 2 per cent., 1 per cent., and 0·1 per cent. solutions of citric acid have been proposed, and are used by various chemists in valuing phosphatic fertilisers. None of these solvents, however, really discriminate between the different phosphates, all of which are soluble up to a certain point, when an equilibrium is established between the phosphoric acid in solution and that remaining undissolved. If the first solution formed is replaced by a fresh portion of the solvent, more phosphoric acid will come into solution; in fact, all the phosphates are eventually completely dissolved by the solvents in question. The following Table shows the amount of phosphoric acid extracted by a 1 per cent. solution of citric acid from one of the Broadbalk soils manured for fifty years with superphosphate, the extraction being repeated with fresh solvent as soon as one portion had been saturated and then removed:—

100 GRAMS BROADBALK SOIL (PLOT 7) WITH 1 LITRE 1 PER CENT. SOLUTION OF CITRIC ACID.

1st Extraction	56·1	mgms.	P_2O_5	dissolved
2nd ,,	22·8	,,		,,
3rd ,,	8·9	,,		,,
4th ,,	6·5	,,		,,
5th ,,	4·4	,,		,,
6th ,,	4·4	,,		,,

Very similar results have been obtained when manures are treated in the same manner, and they may be taken to show that a single extraction of any solvent of the kind proposed will not dissolve the whole of a particular compound of phosphoric acid, which may be thereby distinguished from the rest of the phosphates left unattacked. Such a mode of attack should be regarded as affording only empirical figures to assist the analyst in forming a judgment of the manure; and the conditions of making the solution, such as time, shaking, relative amounts of solvent and substance, must be strictly defined. Furthermore the only solvent which has any *à priori* justification is a solution of carbon dioxide which does the work in the soil; the acids of the cell sap, to resemble which citric acid was taken, have been shown to have no direct contact with the soil particles.

Among the phosphates that are employed as manures, the senior position must be given to bones, the fertilising properties of which have been known from time immemorial. In the eighteenth century we find that their use was an integral part of "Hertfordshire Husbandry," then perhaps the most advanced farming in the country, and but a little later the Cheshire farmers were beginning to build up the richness of their famous milk pastures by the constant use of the same material. So great was the demand that England soon became an importer of bones, taking in 1822, long before the need for phosphoric acid in the nutrition of the plant had been established, as much as 33,000 tons from Germany alone. Forty years later Liebig was moved to one of his characteristic outbursts on this very point. "England is robbing all other countries of the conditions of their fertility. Already in her eagerness for bones, she has turned up the battlefields of Leipsic, and Waterloo, and of the Crimea; already from the catacombs of Sicily she has carried away the skeletons of many successive generations. Annually she removes from the shores of other countries to her own the manurial equivalent of three million and a-half of men, whom she takes from us the means of supporting and squanders down her sewers to the sea. Like a vampire she hangs upon the neck of Europe, nay, of the whole world, and sucks the heart blood from nations without a thought of justice towards them, without a shadow of lasting advantage for herself"! Well Germany is paying herself back now by taking our sulphate of ammonia and our basic slag.

Though no longer the unique source of phosphoric acid, bones are still a very important element in the fertiliser trade; last year we imported 47,346 tons, the home production being rather greater. In the main these bones get sold in three forms; after treatment with acid; in the raw, ground-up condition, only the fat having been removed, as bone meal; and thirdly, after they have been degelatinised and the greater part of the nitrogen removed, as steamed bone flour. Raw bones or bone meal, though the price has been at a low level for some years, still seem to be rated too highly; the nitrogen of the phosphoric acid they contain being over-valued if we take into account their availability as shown by field experiments. Practically, all the experiments go to show that bone meal is so slow in its action that quite excessive amounts have to be used and locked up in the soil, if any immediately appreciable result is to be obtained.

Nor is the reason far to seek; owing to the toughness of the ossein structure of the bone it is a matter of difficulty to reduce it to a

really fine state of division, at any rate the bone meal of commerce is a comparatively coarse powder. Now it has already been pointed out that a tricalcic phosphate, such as exists in bones, is very far from insoluble in water charged with carbon dioxide, but, as with all sparingly soluble salts, the rate of solution will be proportional, other things being equal, to the amount of surface the solid exposes to attack, and for a given weight of material this increases in the same proportion as the average diameter of the particles decreases. In consequence, for all the insoluble phosphatic manures fineness of grinding is perhaps the most important factor, upon it more than even upon the chemical composition depends the availability of the fertiliser to the plant. Bone meal is slow-acting and ineffective because it is coarse, nor is the valuable phosphoric acid brought into solution more readily in the second year than in the first, because the coarse condition still persists. The availability of a phosphatic fertiliser might even be reckoned as the product of two factors, a solubility factor depending upon its chemical composition, and a second factor—the area of surface of unit weight of the material.

If bone meal has been overrated, on the other hand steamed bone flour has not received the credit it deserves. In the first place analysts have rather warned the farmer against steamed bone flour, as representing in some way a spurious bone meal from which the nitrogen had been illicitly extracted. The warning is needful enough if the steamed bone flour were in any way being passed off as bone meal, but provided it is sold on its own basis as a material containing nearly sixty per cent. of tri-calcic phosphate and one per cent. or so of nitrogen, it is a better manure than bone meal. The fine grinding allows the phosphates to pass into solution, and the ossein of raw bones, in which their nitrogen is present, decays so slowly that it becomes one of the most ineffective of fertilisers.

The next phosphatic deposit to receive much attention was guano, which has already been mentioned as a nitrogenous manure. Properly speaking the term guano should be restricted to material, consisting almost wholly of the excreta of sea birds, which has accumulated upon certain oceanic islands in the more rainless districts of the earth, where the birds habitually nest in vast numbers. The best known and richest of these deposits occur off the coast of Peru between the 7th and 20th parallels of south latitude, but similar deposits have been found upon islands on the west coast of South Africa (Ichaboe and Damara Land), the Pacific (Baker, Abrohlos, Christmas and Ocean Islands), Bolivia (Mejillones), the West Indies (Aruba, Navassa, Sombrero), and many other places. The original deposit is mainly a nitrogenous compound, and as may be seen from the analysis previously given of Chinchas guano (a deposit known to have accumulated within the last forty years) it may contain as much as 18 per cent. of nitrogen and only 9 per cent. of phosphoric acid. The action of the weather, particularly where the climate is not absolutely rainless, is always removing the nitrogenous compounds, so that the proportion of phosphoric acid tends to increase, until even among the Peruvian deposits a guano is found on Lobos Island containing little more than 2 per cent. of nitrogen and 60 per cent. of phosphate of lime. In some of the other deposits that have been enumerated, Christmas Island, for example, the nitrogen has entirely disappeared and a phosphate rock is left behind, which can only be termed a guano in virtue of its origin. These purely phosphatic deposits, many of which are now exhausted or no longer pay to work, have been so much mineralised that they are not sold as guanos but are employed for the manufacture of superphosphate. However, the Lobos phosphatic guano is still extensively imported, and being naturally soft and in a fine state of division, it can be applied without treatment to the land, and forms one of the most valuable of the neutral phosphates that are so well adapted to light soils. With the exception of the Peruvian deposits and those from the Pacific, Christmas, and Ocean Islands, practically none of the other deposits are now worked.

In 1845, when the use of phosphatic manures was beginning to arouse general attention, Professor George Henslow called the attention of agriculturists and manure makers to the coprolites which occur over a considerable area of the eastern counties as a bed about a foot thick at the top of the lower greensand formation or at the bottom of the gault. These coprolites, which take the form of pebbles containing 50-60 per cent. of calcium phosphate and 20 per cent. or so of calcium carbonate, consist of concretions of phosphate of lime deposited round excreta, fragments of bone and shell, shark's teeth, &c., and were for many years mined in Bedfordshire, Cambridge, Suffolk, &c.; the output being as much as 50,000 tons per annum in 1884, though now it

has entirely ceased owing to the competition of the richer deposits which have become available. Similar deposits were worked in France, Belgium, and Germany, generally in rocks of cretaceous age, but they attain their greatest development in Florida, Tennessee, and South Carolina. There in many places the subsoil is a sandy deposit full of coprolitic pebbles, which can readily be separated by screens or washing; the beds of the rivers and creeks, again, are wholly composed of the same pebbles which are recovered by dredging. The river deposits have been particularly valued in Great Britain for superphosphate making, because though they only contained about 60 per cent. of phosphate of lime they were particularly free from iron and alumina. About 150,000 tons per annum used to be imported, but of late years the supply has been falling off. The various phosphate deposits in North America yielded in 1901 nearly 1,600,000 tons, of which more than half was exported to Europe.

Just as it is impossible to draw a line between the recently formed true guanos and the weathered deposits which have practically become phosphate rock, so again no real distinction can be made between the guanos and coprolites of known origin and the phosphate-bearing strata, which are to be found in many countries, and at all geological horizons. Many of these may have originated in guano beds, others are coprolitic, others again are due to solution of phosphate of lime, originally diffused through a great mass of rock, and its concentration in a single layer. In all cases, however, the material has been of animal origin, whatever processes of solution and redeposition it may have suffered since. In the older rocks the phosphate has often become crystalline, forming the hard mineral known as apatite and mined on a small scale in Canada and Norway. The Estramadura deposits were perhaps the first of the rock phosphates to be described, though they were not much worked until the seventies of the last century. Lahn phosphates from Germany, and the Somme phosphates from the north of France were the most largely exported of these rock deposits, until the first of them was wholly and the latter partially displaced by the discovery of richer American deposits. However, these are now in their turn yielding to the competition of the great deposits of phosphate rock which have been discovered in Northern Africa, and which are now being exported in immense quantities from Algeria and Tunis. The phosphate bed appears to stretch right across the continent, but Morocco has, naturally, not been explored, while the Egyptian rocks as yet examined are hardly rich enough in phosphoric acid for export, though immense beds exist containing 40 to 50 per cent. of tricalcium phosphate. The most important of the phosphate mines in North Africa occur in the province of Constantine in the district of Tebessa, from whence they extend into Tunis, near Gafsa. The rock is generally at the base of the eocene system, and occurs in strata that may be 2½ or 3 metres thick and contain as much as 60 per cent. of calcium phosphate, which may be raised to 70 per cent. by picking over. These African phosphates contain but little iron and alumina, and are rapidly becoming the chief material for the manufacture of superphosphate in this country.

The mineral phosphates have been but little employed directly as manures, though there is plenty of evidence that when they are really finely ground they are effective enough on soils retaining plenty of water, and particularly on those of a peaty nature. Recent German experiments also indicate that such ground mineral phosphates are most available when mixed with ammonium sulphate, which, as already explained, acts as a physiologically acid manure and helps to bring the phosphoric acid into solution. In the main, however, the mineral phosphates are used in the manufacture of superphosphate, practically the only manure containing phosphoric acid at all readily soluble in water.

The first published reference to the use of sulphuric acid to produce a soluble phosphate appears to be in Liebig's Report to the British Association in 1840, in which he recommends that bones should be so treated. However, there is very little doubt that various people in this country had previously made what we now call dissolved bones for agricultural purposes; indeed, in the same year, 1840, Lawes was trying a superphosphate made from bone ash on a comparatively large scale on his own farm. Lawes's private experiments began in 1837, and during the next year he was asked if he could not turn spent animal charcoal, bone char, or bone ash, of which large quantities were available as a waste product in London, into something useful as a manure. He tried it in his plot experiments, and found its efficacy much increased by treatment with sulphuric acid; by 1840 his plot experiments had been exchanged for large scale trials in the field. Lawes took out his first patent for treating mineral phosphates with acid in 1842:—
"Phosphatic substances have heretofore been

employed as manure, but always, to the best of my knowledge, in a chemically undecomposed state, whereby the action on the soils to which they have been applied has been tardy and imperfect. It is in particular well known that in the case of a large proportion of the soils of this country the application of bone dust is of no utility in producing crops of turnips on account of the slow decomposition of bone dust in the soil and the consequent exposure of the young plant for a long time to the ravages of the turnip fly." Lawes found it necessary to disclaim the application of acid to bones in his patent, confining it to "phosphatic substances, apatite, or phosphorite," and it was on this basis his manufactures began. Since also Liebig, in his many controversies with Lawes, never claimed against him any priority in the use of sulphuric acid to dissolve phosphates, it may be concluded that prior to 1840 the use of acid to attack bones was common knowledge, and that Lawes's application of it to mineral substances was his own idea and not derived from Liebig.

At first bone ash and bone char were the phosphatic materials used in the manufacture of superphosphate, then followed the discovery of coprolites, developed in the eastern counties by Packard, after which the various foreign phosphates already enumerated followed in rapid succession. In the manufacture of super a rich phosphate of lime is desirable, containing for the high grade supers at least 70 per cent. of tri-calcium phosphate, with as little oxides of iron and aluminium as possible and a few per cents. of calcium carbonate. The latter, though it wastes sulphuric acid by giving rise to an excess of gypsum, results in a dryer and more friable super that can be readily handled in the drill.

The phosphates of alumina and iron are undesirable because they give rise to sulphates of these metals and free phosphoric acid, which, however, slowly change back into the original substances on storage of the manure. Hence the proportion of phosphoric acid soluble in water immediately after manufacture declines, and in its place are found precipitated phosphates known as retrograde or reverted phosphate, which are not taken into account in the British method of estimating superphosphates by the water soluble phosphoric acid only. The exact value of these phosphates is a matter on which opinions are divided, but at the present time the question is less pressing, because of the abundance of raw material practically free from iron and aluminium. When superphosphate is applied to the soil the soluble phosphoric acid it contains is rapidly reprecipitated; to some extent the clay provides the necessary base, but on most soils the calcium carbonate takes the chief part in the reaction, with the production of the di-calcium hydrogen phosphate. As this precipitation takes place all throughout the soil the phosphate is very finely divided and thoroughly disseminated, hence the great effectiveness of superphosphate. How thorough the precipitation of the phosphoric acid is within the soil may be seen from Dr. Bernard Dyer's examination of the soils from the Broadbalk wheat field which had been receiving $3\frac{1}{2}$ cwt. per acre of high grade super for 50 years previously. He found that though the surface soil to the depth of nine inches had been enormously enriched in phosphoric acid soluble in 1 per cent. solution of citric acid, the subsoil below had practically gained none, so complete had the precipitation been in the layer stirred by the plough. Again, the drainage waters from these plots show a most trifling amount of phosphoric acid, so that losses by washing out must be negligible. Still more cogent evidence of the retention of phosphoric acid by the soil has been obtained more recently by applying the method of successive extractions with a 1 per cent. solution of citric acid until the phosphoric acid going into solution has fallen to the low constant figure indicating the solubility, not of the recently added, but of the original soil phosphates. About five extractions remove the

TABLE XXI.—Phosphoric Acid Soluble in five extractions with 1 per cent. Citric Acid compared with that in Manure and Crop. (Rothamsted, 1904.)

phosphoric acid down to this point; further extractions removing very little more, and the sum of the phosphoric acid dissolved in these five extractions approximates very closely to the surplus of phosphoric acid supplied as superphosphate over that removed in the crop.

This shows that phosphoric acid supplied as superphosphate remains in the surface soil, and in a form that is readily soluble in weak acids such as a dilute solution of citric acid or the natural solution of carbon dioxide occurring in the soil. Doubtless the result would be modified if the soil were not well provided with calcium carbonate, in which case more insoluble phosphates of iron and alumina would be formed. It is a fair conclusion to draw from these results that super, and indeed, all phosphatic manures, may be applied to the land much earlier than is usually the case; because there is not the least fear of their washing out, and it is all important to get them well disseminated through the soil by solution and reprecipitation and by cultivation. For the turnip crop there may perhaps be some advantage in drilling the manure with the seed, so important is it to have the young roots stimulated by an abundance of phosphoric acid close at hand, but with other crops much of the benefit of phosphatic manures is often lost because they are applied when the land has already begun to run short of water. Fine grinding and early application are the two great factors in making phosphatic manures available.

There remain for consideration two other phosphatic manures which form a class apart, in that their reaction is alkaline instead of being acid or neutral as in the cases already dealt with. One of these manures, "basic superphosphate," is manufactured by neutralising superphosphate with enough caustic lime to precipitate the soluble phosphate as dicalcic phosphate or retrograde phosphate and also to leave a small excess of free lime in the mixture. It is recommended for the lighter soils lacking in calcium carbonate and in consequence unsuited to superphosphate. These soils are also, as a rule, too dry for basic slag. Basic superphosphate has not as yet been put to any systematic test against other sources of phosphoric acid; its fineness of division should, however, do much to make it effective.

In the other alkaline phosphatic manure, "basic slag," the phosphoric acid is supposed to be present as a tetra-calcium compound, which, however, is readily attacked by acids as weak as the solution of carbonic acid in the soil, it is thereby split up into dicalcium phosphate and calcium carbonate, so that in such media it becomes more soluble than tricalcium phosphate. In the basic slag of commerce there is always some phosphorus present as phosphides rather than phosphates, and how far these compounds ever become available for the plant has never been investigated. There is also always in basic slag an excess of lime over that which is combined with the phosphoric acid, silica, &c., but there appears to be little definite information about the amount that is left free in this way. Considering the importance of the basicity of the manure, it is rather curious that so little attention is paid to this point in the ordinary analyses for commercial purposes.

The story of the manufacture of basic slag and of the discovery of its fertilising properties when merely finely ground has been told so often, and is so much a matter of recent history that there is no need for me to repeat it, but introduced into the fertiliser trade so recently as 1886, at the present time about 300,000 tons are manufactured annually, of which 120,000 are exported.

The immense success of basic slag has in this country been mainly due to its special power of improving a particular class of poor grasslands on clay. The soils of these clays are naturally lacking in both phosphoric acid and carbonate of lime, and when they have been long down to grass they become covered with a thin poor herbage of "bent" grass (*Agrostis*), which creeps along the surface in straggling tufts and affords very poor grazing for any kind of stock. Farmyard manure and almost any form of nitrogenous fertiliser have no good effects, often an injurious one, but the summer following a dressing of basic slag the whole pasture becomes covered with white clover, small plants of which had previously been living stunted beneath the bents. Stock now graze the land with great relish, and the vegetation year by year improves, the *agrostis* giving place to clovers and other grasses of better character. One of the great factors in this change is the lime in the basic slag. It renders available some of the reserves of potash and nitrogen in the soil, and of the latter there is a great accumulation in any old pasture. Both by its alkaline reaction, its liberation of potash, and the aeration it induces by flocculating the clay when some of the lime is washed into the soil as calcium

bicarbonate, it aids the phosphoric acid to render the soil favourable for the growth of leguminous plants, hence the sudden appearance of the hitherto dormant white clover. The white clover is always closely grazed, and as it collects nitrogen from the atmosphere, the whole herbage on the land, grasses as well as clovers, is improved year by year.

On some soils it is well-known that basic slag has no visible effect, there is neither the general improvement in the growth of the grass, nor the sudden appearance of white clover which leads to the permanent enrichment. There are three factors which may be operative in bringing about this comparative uselessness of basic slag. In the first place on some soils the dormant plants of white clover do not exist or are present in such small numbers as to be inappreciable in the first year or two following the application of the manure. As Professor Middleton has shown, it is necessary in these cases to follow up the application of basic slag with a seeding of white clover, harrowed into the land.

Secondly, on sandy soils, with little clay in their composition, there is no reserve of potash compounds to be rendered available by the lime of the basic slag; the Rothamsted experiments show very clearly that it is potash which pushes on the clovers in grass land, and that phosphates do very little for them in the absence of lime, hence when basic slag can act only as a phosphatic manure it will benefit the leguminous crops but little. In such a case potash manures must be used with the basic slag. Lastly, the visible effects of basic slag are always smaller on land newly laid down, simply because there is not the accumulation of nitrogenous material from past crops which characterises old grass land. The lime in the basic slag renders some of this reserve material available for the herbage, the increased supply of nitrogen being apparent in the fuller green the grass assumes.

It should not be supposed, however, that in any of these cases the basic slag is without value because its application is not visible; phosphatic manures never have the effect upon the growth and colour of the crop which nitrogenous manures have, so that they can only be properly judged by the weight and quality of the crop at harvest time.

The question is often raised of how far the improvement effected on grass land by basic slag is permanent and likely to be repeated if the treatment is continued. Only one constituent of a crop is being supplied, the phosphoric acid, whereas potash and nitrogen also are being taken away, having been obtained from the soil through the action of the lime in the slag. When the land is being grazed, however, nearly all the potash and a large proportion of the nitrogen in the grass are returned to the soil in the excreta of the animal; at the same time the clovers are drawing nitrogen from the atmosphere, so that there is no practical loss of fertility. At any rate, feeding out a little cake, which is justified by the improvement in the feeding qualities of the pasture, will more than compensate for any withdrawal of nitrogen. When the land is hayed the case is different, because there is a much greater removal of nitrogen and especially of potash. The Rothamsted experiments show that when only phosphates and potash are supplied to grass land, though the leguminous plants become the characteristic features of the herbage, they cannot collect nitrogen fast enough to furnish a large crop of hay year after year, hence a profitable hay crop cannot be grown continuously without some external supply of nitrogenous fertiliser. When potash also is withheld the land soon becomes impoverished; with phosphates alone the effect is good at first, but in the end the land becomes poorer than if no manure at all had been supplied, because the draft on the potash and nitrogen originally present in the soil has been increased. Hence, after the first few years, when the reserves of potash in the soil set free by the lime of the basic slag have been somewhat reduced, potash manures will be required. Under more ordinary conditions of farming when the land is sometimes grazed and sometimes hayed, it may be said that after the first four years or so of great improvement of the land by basic slag, then cake feeding, and perhaps a little nitrate of soda for the hay crop is necessary to keep up the nitrogen supply, and that subsequent applications of basic slag should be accompanied by some potash manure.

SIXTH ORDINARY MEETING.

Wednesday, January 16, 1907; Sir WILLIAM PREECE, K.C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Amsberg, Simeon Ernest, Penang, Straits Settlements.

Bose, Asok, University, Birmingham.

Braithwaite, James E., 6, South-parade, Leeds.
Burt, Andrew, M.I.M.E., M.Am.I.M.E., Fleets-house, Tranent, N.B.
Buyzer, Charles Allan Oswald, F.S.I., 128, Hultsdorp-street, Colombo, Ceylon.
Campbell, William Archibald, 144, Warren-avenue, Chicago, Illinois, U.S.A.
Chaussé, Alcide, 1051, St. Hubert-street, Montreal, Canada.
Dadachanji, Rustonshaw K., B.A., LL.B., Kalbadevie-road, Bombay, India.
Edwardes, Stephen M., Highfield, The Ridge, Malabar Hill, Bombay, India.
Emslie, B. Leslie, Dominion Agricultural Offices of the Potash Syndicate, 3, Holbrook Chambers; 104, Sparks-street, Ottawa, Ontario, Canada.
Hogg, John, 13, Paternoster-row, E C.
Humphries, Albert Edward, Balfour-road, Weybridge.
Johnston, John, B.A., The Villiers Endowed School, Limerick.
Kamm, Director, The Rigibahn, Goldau-by-Zurich, Switzerland.
Khan, Ahmad Hosain, B.A., Sessions Court, Jhelum, India.
Law, J. A., Birkbeck Bank-chambers, Chancery-lane, W.C.
Middleton, Professor Thomas Hudson, M.A., Board of Agriculture and Fisheries, 4, Whitehall-place, S.W. and University, Cambridge.
Pennant, Claude Douglas, 2, Mitre-court-buildings, E.C.
Rowntree, Bernard, 20, Queen-square, W.C.
Schenck, F. E. E., Studio, 1A, West-street, Pimlico, S.W.
Seaton, Mrs. Ellen Jeannette, 93, St. George's-square, S.W.
Tatsuno, Professor Kingo, M.E., Imperial University, Tokyo, Japan.
Tyler, William Ferdinand, Royal Societies Club, St. James's-street, S.W.
Wilson, Fred., 24, Palace-gardens, Enfield, N.

The following candidates were ballotted for and duly elected members of the Society:—

Bainsmith, Mrs. Georgina Fairholme, St. Ives, Cornwall.
Cuthbertson, Ebenezer, 33, Arncliffe-gardens, West Hartlepool.
Flurscheim, A., Chancery-lane Station-chambers, 31, High Holborn, W.C.
Habell, Frank Stannah, care of Messrs. W. Hill and Co., Elderslie Rock Blasting, Renfew, near Glasgow.
Higgins, Eric, 5, Oak-terrace, Fairfield, Liverpool.
Honey, Richard, 2a Providencia, Mexico City, Mexico.
Honey, Thomas P., 2a Providencia, Mexico City, Mexico.
Ibbs, Miss Edith A., 3, Endsleigh-gardens, N.W.
Keen, Walter Henry, Portland-lodge, Atkins-road, Clapham-park, S.W.
Raegener, Louis C., 141, Broadway, New York City, New York, U.S.A.
Roberts, James, 1, Paper-buildings, Temple, E.C.
Shafi, S. M., 54, Poonamallee High road, Parktown Post, Madras, India.
Street, Arthur William, 37, Hamilton-square, Birkenhead, Cheshire.
Thompson, Charles, 11, Norfolk-street, Strand, W.C.
Wilson, George, C.B., Hans-crescent Hotel, Hans-crescent, S.W.

The discussion on Mr. J. W. GORDON'S paper on

"PATENT-LAW REFORM,"

was resumed—

Sir LLOYD WISE, in resuming the discussion, said the subject of the measures to be adopted under the Patent-law for adequately protecting English manufacturing industries without unfairly handicapping the inventor was by no means a new one. It had been discussed over and over again within the last thirty or forty years, and he was very glad that the author by his able paper had afforded an opportunity for discussing it in the light of later experience at the Society of Arts, where so many fruitful discussions on Patent - law reform had taken place. The author realised that in certain cases at the present time the Patent-laws operated in a manner which might be oppressive to certain manufacturing industries. One of the remedies suggested was a reconsideration of the practice with regard to the granting of injunctions. He could not presume to place his experience on such a point against that of so able a lawyer as Mr. Gordon, but so far as his experience had gone he had not found that Courts were excessively ready to grant injunctions; at any rate, they would not usually grant an injunction until the case had been tried, and it had been proved to their satisfaction that there was a sound patent, and it had been infringed. Opinions might differ, he admitted, as to whether a patent was sound or had been infringed, but they had to bow ultimately to the tribunal whatever the decision might be. According to his experience, the Courts were not in the habit of granting injunctions until they had satisfied themselves, and the author had not succeeded in persuading him that it would be desirable to abolish the practice of granting injunctions. The objection taken to the present state of affairs was that patents were acquired in this country by foreigners, who carried on their manufacture abroad, importing the manufactured articles into England, and that in this way home manufacturing industries suffered, and much employment was lost to the working classes. That he believed to be true, and it was a condition

of affairs for which he should very much like to see an efficient remedy, but the question was how to cure that mischief without imposing unreasonable conditions upon the average inventor. Besides having a very liberal system of compelling the granting of licenses in return for reasonable consideration, a system which would afford widespread protection to home manufactures, it seemed to him that the Act of 1902 might be somewhat developed. That Act contained a provision which pointed in the right direction, viz., that if it be proved to the satisfaction of the Judicial Committee that the patent was worked, or that the patented article was manufactured exclusively or mainly outside the United Kingdom, then unless the patentee could show that the reasonable requirements of the public had been satisfied, the petitioner should be entitled either to an order for a compulsory license, or to an order for the revocation of the patent. If they followed that idea out, might they not reasonably come to this, that it should rest with the patentee, whose patented manufactures were being imported into this country, to show, if called upon, that the manufacture here was taking place to at least an equal extent? Could they not, for the Privy Council, substitute a much less expensive tribunal? It seemed to him that if they could arrive at that, they would wipe out the difficulty and the danger which so many people complained of. He did not suggest that compulsory licenses should necessarily be in substitution for the revocation of the patents; but what he did desire was that, unless there could be shown any exceptional reason to the contrary, the patent of a man whose patent was being worked by importing more than was being manufactured in this country, should become liable to revocation—not, however, without first ascertaining the position and giving reasonable notice that revocation would ensue if the practice were continued. He made that proviso because he thought that where it was found that patent privileges were being abused, it was reasonable that the facts should come before some responsible tribunal, in order that it might be ascertained before revocation of the patent took place, whether there was really sound and conclusive reason why the manufacture should not take place in this country. If they could give an opportunity of showing that there were commercial reasons which rendered it practically impossible that the manufacture should take place here, then that might be allowed to go, because in that case nobody would suffer, and they ought not then to revoke the patent. It was most important that patent property should be liable to as little uncertainty as possible. One of the objections to the laws of most foreign countries in which there were compulsory working provisions, was that a patentee never knew, until too late, whether he had done enough to satisfy the law, or not. That, certainly, was not a state of things that they would like to see established in this country; but he did wish to see a condition of affairs established that would give the preference to our own manufacturers, as distinguished from manufacturers carrying on business abroad. He felt very strongly in support of some reasonable system which would have that effect. With regard to the tribunal which in his view should be entrusted with questions of that kind, he was afraid he would find himself in a terrible minority, but he maintained that an authority which was charged with the consideration of applications for patents, with the question of determining whether an invention sought to be patented had been already patented, or whether it had been stolen from the person who opposed the granting of the patent, and questions of that kind, or whether an amendment which it was sought to make was reasonable and legitimate—he submitted that a tribunal which could be trusted to deal with matters of that kind could readily, if well developed, constitute an admirable and a comparatively economical tribunal for enquiring into the facts of cases in which it was alleged that importation into this country was taking place on a larger scale than manufacture here, and whether there was a reasonable excuse for that state of things. Until about two years ago the Canadian Patent-law required in all cases that manufacture in Canada should take place within a certain time from the date of the patent. For a long time, under a decision of a former Commissioner of Patents, it had been considered that so long as the patentee was prepared to grant licenses on reasonable terms, or to supply the patented article if asked for it, the law was complied with. A time came, however, when it was suddenly decided by a higher tribunal that that was not sufficient, and consequently legislation became necessary. He took the opportunity, when consulted on the subject, of suggesting the provision of a compulsory licensing system in lieu of the compulsory manufacturing provision, but in amending the law provision was made for applying to the authorities, either to have the patent put under the compulsory working clauses, or under the compulsory licensing clauses. The application so made was dealt with according to the character of the invention, and the view taken of the matter by the authorities. When a patent had been placed under the compulsory license clauses—and in that connection he should like to say that he found that practically all British and Continental applicants for Canadian patents had asked to have their patents placed under those clauses—when so placed the application for a compulsory license could be made by anybody and was dealt with by the Patent-office authorities. Canada was not the only country in which the Patent Office authorities performed analogous duties, and it seemed to him that the idea which obtained in this country, that to deal with matters after a patent was once granted the tribunal must be of a cumbersome and costly character, should be dispelled. He believed the tribunal he had suggested would be an efficient one, and that it would do its work quickly and give general satisfaction. With regard to the final

revocation of a patent in a case where it appeared that the patent ought to be revoked, he would suggest that after enquiry by the Patent Office tribunal their report might be referred to the Court. He should like to see some restriction, so that such a question would not have to go from a Court first instance to the Court of Appeal and from the Court of Appeal to the House of Lords. He thought that people of moderate means were at any rate entitled to expect some opportunity of getting justice.

Mr. JAMES ROBERTS said the author had told them that under the Statute of Monopolies patents were granted so long as they were neither "contrary to law, nor mischievous to the State by raising prices of commodities at home, or hurt of trade, or generally inconvenient." The reason why monopolies were granted at all to inventors was to reward the inventor for the good he did to the public by introducing a new industry into the country, not only by inventing a new thing, but, in the early days, the award was made for introducing a manufacturing industry into the country. They wanted to get back to that state of things, which they had drifted from for reasons now historical, such as change of trade and trade methods, change of intercommunication, and so on. The law, which at first was intended to protect British industries, had now come to be used in certain instances to protect the foreigner by the strongest protection he could have against the British workman, by having given him a monopoly to make the goods abroad and bring them into this country, and sell them at what price he could get. His suggestion was, that it would be better, as regarded compulsory working, to go to the root of the matter at once, not to enquire whether the amount of manufacture was equal or more than what was manufactured abroad, but to say at once that a patent should be liable to be revoked if the patentee imported into this country goods which, if imported by a stranger, would be an infringement. If the patent was worked at all, then it must be worked in this country. Of course, there were exceptional cases where it was impossible to work the patent in this country for commercial reasons, such as the price of raw material being too high, and in that case the onus should be on the patentee to show it, and if he did so he should get permission to import. By looking at the question from that point of view, the evil was at once reached, and all enquiries, such as whether the public were already supplied sufficiently or not, were done away with. That, suggestion, however, did not stand alone. With reference to the blocking of patents, the monopoly was intended simply to reward the inventor, and it was incidental to that reward that the inventor should have a monopoly. Now if the inventor could be rewarded by royalty without being given the evils of monopoly, he thought it was in the public interest that a change should be made. That would mean giving compulsory licenses practically to any manufacturer of standing who wanted one. If the question was looked at from this point of view, the result of it would be that there would be free competition in the manufacture. Five or ten manufacturers might apply for a license, and having got it would then compete against each other, and whatever virtue there was in free competition, the public would get the benefit of it. To the extent that the public benefited by the manufacture of new goods, to that extent proportionately the inventor would be rewarded. In this case, too, there must be a limit, and he suggested that the patentee should have a right to enquire before the license was granted as to whether the proposed licensee would be substantially able to meet his royalties. It would not do to let any bogus company get a license for the working of the invention. Another evil the author had referred to, was the tacking on to licenses of all kinds of conditions which were never contemplated originally. That evil, he (the speaker) thought arose in a very simple way. It arose from the earlier decisions, in which it was held that when a man once manufactured under his patent, and had sold his manufactured article, the purchaser of that article could do what he liked with it. The ground of the decisions was that he had an implied license to do what he liked with it by the fact of the purchase, and therefore it was implied that such implied license could be negatived by express agreement. This implication was contrary to the laws of other countries and our Colonies, which said that conditions could not be attached to personal property. He thought the remedy in that direction would be simply to enact that any breach of a conditional license should not be deemed to be an infringement, but only a breach of contract. He would not go into the question of the nature of the tribunals, because that had been discussed much better by others, but as regarded the general principle of substituting a court or a tribunal of some kind to fix licenses instead of leaving it to open competition he thought there was much to be said in favour of it. The principle was admitted in the Acts of 1883 and 1892. There was no knowing what prospect the Bill now before Parliament had of passing, but he hoped sincerely that it would pass, and that if it did credit would be given to the draftsman and the other gentlemen, who had for years past been so insistent in their endeavours to get it passed.

Professor BOYS, F.R.S., after speaking in eulogistic terms to the scholarly character of the paper, said he desired to refer generally to the questions of the compulsory license, and the harm done in this country by the power that the English Patent-law gave to foreign financial groups. Even in his small experience he had seen cases where the English manufacturer was entirely shut out by the definite determination of those who held the English patent that not a thing in connection with it should be done in this country. Departing from a consideration of the great fundamental principles which were being

discussed with the hope of a change in the law, and referring to minute details which he supposed did not necessarily require a change of law, he wished to mention the difficulty which everyone who had had to examine many specifications was only too familiar with in connection with the complicated small drawings by which they were accompanied. The drawings were made in black and white because of the process by which they were produced, the result being that when the drawing was not for a simple piece of mechanism, but for a complicated piece of machinery in which one thing was seen behind another, and that behind something else, it was necessary throughout their length following out the lines to strain the eyes so as to tell whether any individual line was the right-hand edge of something to the left or the left-hand edge of something to the right. He found it practically necessary, in order to make these drawings clear, to pick out the parts with a red and blue pencil, and sometimes also with one or two other colours, and then the whole difficulty of following what the construction really is vanishes, complication changes to simplicity. Now he wanted to ask whether modern improvement in colour printing were not available so that such drawings as he referred to could be printed where necessary in two or three colours, the patentee, of course, supplying separate drawings in black for each colour that is required, and writing upon the drawing the name of the colour. Then if certain fiducial marks were made, also in black, of course, any want of perfection in register would be indicated by the displacement of the fiducial marks upon the composite colour print. If any snch scheme could be considered practicable, the increased clearness of the drawings and facility of interpretation would be a great advantage.

Mr. EDWARD CARPMAEL did not think that Mr. Gordon had made out his case for the abolition of injunctions. All his arguments seemed to be based upon most unusual and extraordinary cases, and even as to some of those he hardly thought that the remedy was applicable. Again, legislation based on exceptional cases was proverbially unsafe. He thought also that Mr. Gordon had overlooked the fact that in many cases, although the damage done by infringement to the patentees' trade was very real, it was extremely difficult either to estimate or prove. He was, however, content to leave this branch of the subject to others more competent than himself, but would like to speak for a few minutes upon a subject which cropped up incidentally, viz., compulsory working. Mr. Gordon appeared to be a sort of half-hearted supporter of that, provided it was limited to patents which were worked abroad, but not in this country; and at the last meeting Mr. Levinstein strongly supported that view. Now he (Mr. Carpmael) did not think those gentlemen could have fully appreciated Article 2 of the International Convention. By hat article was agreed to give foreigners equal rights with Englishmen in all matters relating to patents. But as a matter of fact 99 out of every 100 patents which were worked abroad but not here were the property of foreigners. Could we, therefore, say that a law which applied only to those patents would give equal privileges and advantages to foreigners. It appeared clear that such a law was contrary to the spirit of the Convention, and indeed the advocates of the law openly said it was directed against foreigners, and especially against the Germans. If compulsory working was established in the country there were only two alternatives, either we must secede from the International Union, or the law must apply to all patents equally. He did not think anyone supported the first alternative. Indeed, the advantages this country had gained from the International Convention were so great that it would be madness to give them up. Moreover, there were grave objections to the other alternative, some of which had been mentioned by Mr. Gordon and Mr. Levinstein. Thus, as Mr. Gordon had truly said, there were many patents which it was not desirable to work in this country, either because they were for obsolete forms, or else because the article could be produced much more economically abroad so that enforcing the production of it here would entail a greatly increased cost to the consumer. Again, as pointed out by Mr. Levinstein, it took a long time to introduce a new industry, and it would be most unfair, in many cases, to deprive an inventor of all his privileges merely because he had failed to succeed in a time in which, under the circumstances, it was impossible for him to succeed. Such a law was extremely cruel to the poor inventor, who was often crippled for the want of capital. The poor inventor was thus put at the mercy of the rich manufacturer, and a typical case had just come to his knowledge. An inventor having perfected his invention, endeavoured to sell his German patent to a large manufacturer. The latter was quite willing to enter into negotiations, and expressed himself extremely pleased with the invention. But on one pretext or another he allowed the negotiations to drag along, until almost the expiration of the three years allowed for working. The manufacturer then offered about one-tenth of the value of the patent, telling the patentee, "If you do not take this, you will get nothing, for the patent will be revoked for non-working." Again, the greatest objection to compulsory working was not from the point of view of the inventor, but from the point of view of the public. So far from tending to introduce new manufactures into the country, it had an exactly contrary effect. That sounded like a paradox, but it was nevertheless true. The introduction of a new industry required the expenditure of time and money, and in almost all cases at first resulted in a loss. The very object of the Patent-law was to induce inventors and capitalists to face the initial loss by giving them a monopoly for a limited term. What would happen if there was compulsory working, and the monopoly ceased at the

end of three years if the manufacture had not been established? What inducement was there at the end of the three years for the inventor to give further time, or the capitalist to find further money, when all the fruits of success would be reaped by others? None, and the invention was consequently abandoned, often for years, and sometimes for ever. Why was it that capital was much more easily found in this country and in the United States of America for promoting the introduction and exploitation of patents than it was in France and Germany? His answer was that without doubt it was because patents in England and the States were much more secure. In Germany and France no one knew whether a patent was valid, or not, or what was or was not a sufficient working, or a sufficient excuse. He considered it childish to suggest as was done by some that all objections to compulsory working could be removed by giving the tribunal, on whom the fate of the patent depended, a discretion to accept excuses. The result of giving discretion in foreign countries was simply doubt and uncertainty, and capitalists would not find money for pushing inventions. Again, would compulsory working have the effect desired by its supporters? As he understood it the desired effect was to prevent the importation into this country of patented goods made abroad, and especially the importation of dye stuffs made in Germany. But here again the International Convention was a fatal obstacle, for by Art. 5 we had expressly agreed that no patent should be revoked owing to the importation of patented goods, and therefore compulsory working would only have the effect of causing a small proportion of the goods to be made here, whilst the balance could siill be imported from abroad, and he thought that was an answer to one of the speakers. In conclusion, Mr. Carpmael reminded the meeting that this was by no means the first time that the "compulsory working" had come before the Society. At a very full meeting six years ago, when a paper on the subject was read by Mr. Alexander Siemens, the speakers unanimously condemned the suggestion, and he trusted the Society would adhere to the opinion then expressed, and use their utmost endeavours to prevent the passing of a law which would be a serious blow to British industries by throwing doubt upon, and consequently diminishing the value of almost every patent without attaining the object of its promoters.

Sir LLOYD WISE remarked that he did not understand Mr. Carpmael's reference to the International Convention. If he rightly understood Mr. Carpmael's view he considered that Sub-section 5 of Section 3 of the Act of 1902 practically rendered it necessary that this country should retire from the International Union, because it provided that if it was proved to the satisfaction of the Judicial Committee that a patent was worked, or the patented article was manufactured exclusively or mainly outside the United Kingdom, then unless the patentee could show cause he should be liable to an order for revocation of the patent. He wished to point out that that proviso applied to all patents, whether taken by British subjects or foreign subjects; and the plan that he suggested applied in the same manner. If that involved this country retiring from the Union, so also would Sub-section 5 of Section 3.

Mr. CARPMAEL entirely agreed with Sir Lloyd Wise that the Act of 1902 was a small breach of the International Convention, but he did not think that was any excuse for following it up with a big one. Two wrongs did not make one right.

Mr. J. F. ISELIN said when he came to the meeting he thought he would represent an unpopular cause, and might even find himself in a minority of one, but after the able observations of Mr. Carpmael, he found that was not the case. His observations would, in the main, be directed to the question of compulsory working. He desired the meeting to notice that the agitation in favour of compulsory working emanated from the manufacturer, and the point of view of the inventor, particularly of the British inventor, had received no considerarion on the part of the people who were proposing the change of the law. One principle to which he desired to draw attention, which had been very much overlooked, was that the patent system was intended not for the encouragement of manufactures but of inventions, and that there was a very considerable distinction between the two. No doubt it would be found stated in the Statute of Monopolies that patents were intended for the encouragement of manufactures, but a good deal of advance had been made in the 280 years which had elapsed since then, and the best opinion of experts favoured the point he was making. He spoke as a lawyer, and a student of systems of Patent-law. Much obloquy had been cast by previous speakers on lawyers, but it could be claimed on the part of lawyers that they had no private interests to serve. It was very significant that when the point which Mr. Carpmael had made, as to the International Convention, was put to Sir Joseph Lawrence by the President of the Board of Trade, he replied that he did not desire foreigners to submit to anything which English patentees would not submit to themselves. It was plain that that meant that English manufacturers wished to have not only the foreign inventor but the English inventor also at their mercy. Sir Joseph Lawrence had also contended that compulsory working was universal throughout the world. He desired to draw attention to the fact that the United States had no system of compulsory working, and that no attempt or suggestion had ever been made to introduce such a system into the United States. It was suggested by the proposers of compulsory working that no great industry could be built up without adopting that system, and yet the United States, without compulsory working, was perhaps the most advanced manu-

facturing country in the world at the present moment. Upon the Continent of Europe, where they had much experience of compulsory working, the best opinion tended more and more to the abolition of that system. The great international society, which met periodically to discuss these matters, and had held a congress in the Hall of the Society of Arts in 1898, which included representatives from all countries of the world, though Englishmen, unfortunately, did not take their due share in its deliberations, had repeatedly by large majorities passed resolutions in favour of the abolition of compulsory working, and the substitution for it of a system of compulsory licenses, enforcing the point he was making that the best and most enlightened opinion of the Continent was opposed to compulsory working. The question of compulsory working he also desired to point out was being discussed in the dark. They had been expressly told that the Bill, which was at present under consideration, was entirely a confidential matter. It was not known in what form it was proposed to introduce compulsory working, and it seemed to him that was an extreme instance of the unscientific manner in which the work of legislation was carried out in this country. If the matter was being discussed in Germany the draft law would have been open to the public months ago, and public discussion held on it. Compulsory working could be introduced in two forms, first of all in an open form, and secondly in what might be called a latent form. Either a patent might be revocable when an action was brought forward straightforwardly for revocation, or it might be open to the infringer when sued, to set up the defence that the patent was bad because it was not being worked. The first was substantially the system in Germany and other countries; the second was the system in vogue in France; and the insecurity which it introduced into a patent must be perceived by an intelligent observer. In the case where the patent was revocable only by an action, the unfortunate inventor went to the manufacturer and asked him to adopt the invention, whereupon the manufacturer replied that he had only to wait for a few months and the patent would be void for want of working, and the invention would fall into his hands. But under the French system, the position of the unfortunate inventor was much worse. He went to a manufacturer, who immediately asked what security he had as to the validity of the patent, and argued that he could never tell whether the requirements as to working had been fulfilled in the past, and any infringer could make use of it. Therefore, the natural effect of a system of compulsory working, whether of one kind or the other, was to put the unfortunate inventor, bound hand and foot, into the hands of the manufacturer. From the point of view of the inventor he suggested that the people of this country should be very careful before introducing a universal system of compulsory working, especially remembering that power already existed under the Act of 1902, to declare a patent forfeited for non-working. The Chairman had asked him to discuss the effect of the rules under the 1902 Act. It seemed to him that the existence of the preliminary examination, which was the principal effect of the Act of 1902, did not interfere in the main with the question of compulsory working, but from the public point of view it was a good feature that a man should be prevented from imposing upon the public by means of an alleged invention which anyone who possessed a sufficient knowledge of the matter must know was a bogus invention. He desired to make one small correction to his remarks. He had said there never was a system of compulsory working in the United States, but Mr. Carpmael had drawn his attention to the fact that America once had such a system, which it abandoned for sufficient reasons.

Mr. IVAN LEVINSTEIN remarked that Mr. Carpmael had said that if compulsory working were introduced into this country a breach would be committed of Article 2 of the International Convention; but the International Convention in 1902, held at Brussels, passed the following resolution, indicating that if the compulsory working were introduced, it would not be considered a breach of the International Convention. "The Final Protocol annexed to the International Convention of the 20th March, 1883, shall be completed by the addition of No. 3 *bis* in the following terms:—3 *bis*. The patent in each country shall not be liable to forfeiture on account of failure to utilise it until after the expiration of at least three years from the date of the deposit of the application in the country concerned, and only provided the patentee cannot show reasonable cause of his inaction." That showed that the International Convention approved of compulsory working, and that no breach would be committed against Article 2 or any other article of the Convention. Mr. Carpmael also referred to the initial difficulties which the patentee had to overcome before his patent was really workable, and that it would be very hard indeed to ask the patentee to wait a time, or lose his patent. Mr. Carpmael evidently did not know the terms of the resolution of the Associated Chambers of Commerce, which did not ask for the revocation of a patent because it had not been worked within a certain number of years. The resolution said that if the invention was worked abroad, and goods were imported into this country, the patent should then be liable to be worked under certain provisos. If the British monopoly had been worked abroad and not in this country it was evident that the patentee must have surmounted the initial difficulties, and it was mere cant to say that the poor British inventor would lose his patent because he had not the money to work it. It was quite true that the International Society for the protection of industrial property, the members of which were chiefly composed of Germans and French-

men, passed resolutions seven or eight years ago advocating the abolition of compulsory working clauses in every country. He was present at the meeting, and enquired why the compulsory working clause had not been withdrawn in Germany. Even up to the present time that clause existed in Germany, and would continue to exist, to the very great disadvantage of British manufacturers. It had been stated that America, the leading manufacturing country, had no system of compulsory working, but the answer was a very simple one. With import duties of from 50 to 90 per cent., no compulsory working clause was required, because that of itself was a natural compulsory working clause. Owing to the high prohibitive duties imposed, it was impossible to import goods into the country to compete with home manufactured articles, and inventors were compelled in the majority of cases to manufacture these. It had also been argued that where compulsory working was in force the patents were not secure, but those who had any experience knew that a German patent was a better security than any other patent, so that the suggestion that in countries where there was compulsory working the patents were insecure, might be dismissed.

Mr. CARPMAEL remarked that he did not say that compulsory working was contrary to the International Convention. On the contrary, he distinctly stated it was quite open to this country to have compulsory working. What was not open to this country was to have compulsory working applied only to patents granted to foreigners.

Mr. LEVINSTEIN thought Mr. Carpmael could not have read the resolution of the Associated Chambers of Commerce, which referred not only to foreign patentees but all patentees.

Mr. BURDICK expressed disappoincment that Mr. Gordon did not express any sympathy whatever with the inventor. His sympathies went entirely to the public, who were excluded from the privileges granted by the patent. As to requiring the patentee to manufacture in England in the manner required in most continental countries, he was of opinion that the adoption of the principle was unfortunately made necessary by commercial competition. If, for instance, a German manufacturer or inventor could, by patenting in England, prevent local manufacture, and obtain the benefits of manufacturing for both countries in quantity at a single factory; while the English inventor must establish two manufacturing plants, or transfer the manufacture to Germany, in order to protect himself in the invention, the plan was manifestly unfair; and the only remedy was to adopt the same selfish course as the Continental competitor. From the inventor's point of view he wished to refer—first, to the shortness of the period for which a patent was granted in England; second, the excessive Government fees, and third, certain points of practice which seemed to him unfair. He had learned from a previous paper at the Society, that the inventor was a "visionary sort of person," whose rights in the matter of his invention were scarcely worth considering, and from whom the public should be protected. In America the founders of the Patent-law assumed that the inventor was a public benefactor, and that he should be encouraged, and very favourable laws were made to protect him in his patent rights. The American inventors led the world, and the benefits which they had brought to their own country had been very great. He had no hesitation in saying that the English inventors were not inferior to the American inventors in capacity and brain-power, but that the difference in results was due largely if not entirely to the difference in the laws of the two countries. In America an inventor is allowed two years to experiment publicly with his invention before patenting. He is allowed 17 years of protection from the time that the patent issues, and the entire cost to him was £7. In England the period was 13 years and a fraction, and the taxes for the 12 or 13 years exceeded £100. Many patents were never valuable enough to pay these exorbitant taxes. If the two years of preliminary public trial of the invention allowed by American law were not included, there is a period of about four years in favour of the American patent, which were very often worth more to the inventor than the preceding 14 years. There were certain kinds of accidental inventions, which perhaps should be classed as discoveries instead of inventions, which were perfected, and became immediately remunerative. There were some inventions, such as toys and games, which became obsolete in 14 years; but the more serious work of engineers and chemists often entailed several years of experimental work and a very considerable outlay. He could not find anything whatever to recommend the Patent-laws which came in force in 1905, to the serious inventor. It semed to him that they had been specially drafted by patent agents for their own convenience. While he had to complain about the Patent-laws, he also had a complaint to make in regard to the Patent practice. For instance, an inventor was not allowed that which was novel, and was described in his patent. He was entitled only to that which he claimed, and he was put in the peculiar position that if he claimed more than was novel, his patent became practically valueless, and was indefensible in any Court of Law. It would work no hardship to anyone if the law required a full and complete description of the invention and its application, and the inventor became thereby entitled to that which was novel in it; this was the practice in France, and should be the ruling of every Court. In making a plea for the inventor and his rights, he did not expect that very great changes would be made in his favour. He knew the difficulty of moving legislatures, but he had no doubt that the Society of Arts could affect material improvements if they choose to

throw their influence in favour of the inventor. He did not presume that a reduction in the costs of a patent could be obtained; but he pleaded that a patent should bear date from the time of issue and not from the date of application. It was a popular myth that a British patent was for 14 years. As a matter of fact no patent was granted for 14 years. The inventor had no protection from a patent until it was granted, and it was dated back to the time of his application, which might be many months before. If the American system could be adopted of giving the inventor six months to pay the final fee after the patent was granted, and the patent be valid for 14 years from the date of issue, it would be a substantial advantage to the inventor. The life of a British patent was shorter than that of any other important country, except her colonies, whose laws were modelled after her own.

Mr. Dunbar Kilburn thought Mr. Levinstein was in error in regarding a Germant patent as an infallible asset, because the granting of a German patent did not mean that it was essentially valid. He knew of many instances where German patents had been granted where, if certain material had been brought forward, it would make them not worth the paper they were written on. He desired to endorse strongly everything Mr. Carpmael had said in opposition to the introduction of compulsory working. He thought the attitude taken up by the majority of the speakers was decidedly in opposition to the bulk of inventors, many of whom would suffer pecuniary and other losses if compulsory working in any form was introduced. Certain of the speakers had hinted as he thought a cure for the present state of things, namely, not in the reform of the Patent-laws but a reform in the very difficult and tender subject of protection and free trade. Another point which had been overlooked was that he thought many inventors if they saw that compulsory working was going to be introduced would count the cost beforehand and not take out a patent in the country at all. It would then be in the power of the German manufacturer to introduce his invention without any patent at all, making his goods abroad and selling them at a price at which it would be impossible to compete, and so obtain the benefit he already possessed without any protection at all. The German manufacturer could also start a factory over here with undesirable aliens to assist him at cheaper rates of wages, and undersell in the same way as at present. No Patent-law would be of any use there. Even if compulsory working were introduced the requirements would be got round in various ways as they were abroad, the conditions being only technically complied with. He endorsed all the remarks which had been made against compulsory working, and thought a remedy was to be found in revising the compulsory license clauses, and in other directions entirely outside the Patent-law.

Mr. Gordon, in reply, after thanking the various speakers for the great kindness with which they had attacked him, said that it was impossible for him to deal in a detailed way with every speech, and he, therefore, proposed, as far as possible, to classify the various objections which had been made, and reply to the individual speakers under one or other of the particular heads. Sir Lloyd Wise, Mr. Carpmael, and Sir Joseph Lawrence stated that they were not satisfied with the argument brought forward, to show that the practice of the Courts with regard to the granting of injunctions needed amendment. They thought that people were perfectly satisfied with the present practice, and that it would be mischievous and dangerous to make an alteration. The answer to that was that the objection itself was directed not to what he had said or meant, but to something specifically different. He should be the last to snggest the abolition of the remedy by injunction, which in a proper case seemed to him to be an extremely necessary one. Sir Joseph Lawrence mentioned a case in which if the patentee had had to go through all the Courts up to the House of Lords, he would have been ruined before he obtained his remedy, but personally he did not know what the case could be in which an injunction could be obtained without giving the person restrained by it the right of appeal to the House of Lords. So far as he knew, any person who was restrained by injunction had an appeal through all the Courts up to the House of Lords. Although when the injunction was an interim one the appeal was not often taken, he was very happy to think that so serious a restriction upon their liberty of action as an injunction could not be imposed without giving the right of appeal through all the Courts to the highest tribunal of the realm. He rather inferred that the case Sir Joseph Lawrence had in his mind, was an interim injunction. If that was so, he should like to deal with the objection in that form, because it very pointedly illustrated the exact point he wished to to make. It was a very curious circumstance that when an injunction was granted for a short time the Court always exercised its discretion upon the most approved principles, considering whether it was convenient that the injunction should or should not go. Every question which affected the convenience of the public or of the parties was taken account of when the injunction was not a perpetual, but only an interim one. What he had suggested was that the same careful consideration should be given to the case when the injunction was perpetual as when the injunction was granted ad interim alone. When a perpetual injunction was granted after a trial, the Courts did not pause to consider whether there was any question of convenience involved or not. He knew there were old judgments which said that in all cases the granting of an injunction was discretionary with the Courts, but everybody acquainted with Patent-law practice knew perfectly well that the question of discretion did not arise when an action had been tried out, and, con-

venience or no convenience, the injunction was granted as a mere matter of right. As a very strong instance of the way in which that worked out he would mention an action brought a good many years ago against, he believed, the St. James's Electric Lighting Company for using the three-wire system of distribution for their electricity. The patentee, the late Dr. John Hopkinson, succeeded in his case and obtained an injunction, the terms of which required the company to shut down their works for their distribution of electricity that same afternoon, and leave the whole of their district in darkness until they had time to grub up their mains or rearrange their system so that it did not work upon the three-wire system. Dr. John Hopkinson, however, was a man of high character and public spirit and did not choose to insist upon the injunction. The injunction was granted as a matter of terms, but by his consent it was suspended until arrangements could properly be made; but the important point was that it was not a question for the Court to consider whether the outrageous inconvenience of shutting down the whole electric lighting system on the spur of the moment was a course which should follow from their injunction. His contention was that the public in such a case ought not to have to look for protection to the public spirit of a particular individual but to the law of the land. The serious inconvenience in that case was not half so serious as the inconvenience which was actually inflicted in a case of which the presence of Mr. Levinstein reminded him where an enormous industry in this country was destroyed by an improvident injunction, as a result of which a manufacturing industry was carried over to Berlin and a dyeing industry which had nothing to do with any patentee was taken over to Holland. It must not be supposed that he was dealing with hypothetical cases. Mr. Carpmael had said that extreme cases had been put forward in the paper. He (the author) acquiesced. He contended that he had put forward cases of extreme importance, extreme hardness and urgency, which called pressingly for a remedy. Mr. Levinstein had complained that he (the author) had not done justice to the resolution of the Associated Chambers of Commerce and to the Bill which had been submitted to the Board of Trade. In a sense he pleaded guilty to that charge, and his answer to it had already been suggested by Mr. Iselin, who had stated that that question was being discussed under the great disadvantage that those present did not know what the provisions of the Bill were. That was truer on the last occasion than at present because Mr. Levinstein and Sir Joseph Lawrence had referred to the general nature of the draft Bill. But even now it was impossible to form a definite opinion about the merits of the proposal without knowing more about it than was public property at the present moment; so that if he had done injustice to it, he hoped that that would be a sufficient apology. What he did feel free to say about it was, that there were certain conditions which must be fulfilled in order to do justice to the inventor. It had been stated that he had not expressed sufficient sympathy with the inventor, and had been indifferent to his claims. It was not for him to express an opinion on such a question, but, however inadequate might be his appreciation of the inventor's claims he recognised, fully that he had claims which were of urgent importance in that respect, and that any provision that would impose upon him the duty of compulsory working was one which needed to be guarded with very carefully drawn and fully matured conditions, which Mr. Levinstein assured them were satisfied in the draft Bill. He was content to take it from Mr. Levinstein that that was so, and upon that basis ventured to think that the conclusion that the meeting ought to come to was that it was not impossible that a Bill could be drafted, and a rule framed, which would meet those requirements. He quite believed it was possible, and he said so. And if that did less than justice to Mr. Levinstein's proposals he thought they must wait before doing full justice to it, until the terms of the actual Bill were seen. Passing to the suggestions made by Sir Lloyd Wise, that gentleman had said that this country possessed a very liberal system of granting compulsory licenses, as matters stood at present, and his view was that improvements in the law ought to be developed upon that basis. The meaning of that was that it was a better system than compulsory working. It would be a very large question to go into, and he would not attempt to discuss the relative merits of the two schemes at the present stage. But he desired to point out that the system which Sir Lloyd spoke of as a liberal system had proved itself to be a singularly ineffective one. Three very large volumes of reports of patent cases had been published since the Act of 1902 was passed, and there was not a report of a single compulsory license case in any of the volumes. He could not think that an Act which had had that result, whatever its liberality, could be a satisfactory piece of legislation.

Sir LLOYD WISE, interposing, stated that Mr. Gordon had misunderstood his remarks. What he wished to convey was that a liberal system of granting compulsory licenses, with an economical and readily accessible tribunal, supplemented by a provision for the revocation of patents, where, after due notice, the products imported exceeded those manufactured in this country, would meet the case. It was not his proposition that the present provisions were ample.

Mr. GORDON regretted that he had misunderstood Sir Lloyd Wise's remarks. He found it much easier to understand the case as now explained. There was one point which he made, however, about which he thought he could be under no mistake. It was Sir Lloyd's view that at any rate one important improvement of the law would be to transfer that jurisdiction

to the Patent Office. There was, it seemed to him, a fatal objection to that proposal, which had proved very formidable in two cases already; one where the jurisdiction was vested in the Board of Trade, and, secondly, where it was vested in the Privy Council. The difficulty was that an additional piece of litigation was forced upon the applicant for a compulsory license. The only time when a compulsory license was really and seriously needed, was when an individual was threatened with a patent action, or when a patent action was going to be decided against him. That was a remedy which should be made available to a man when he was before the courts and fighting a patent action. The only tribunal which could effectually deal with the question was the tribunal which had to try the issues in the action. It was an essential and elementary judicial principle that an opportunity of settling the whole controversy in one place, at one time, and by one proceeding, should be given. That was the essence of economy and efficiency in litigation. Individual tribunals might be made as economical as possible, but it was impossible to make litigation economical where an important property was at stake as when the validity of a valuable patent was under consideration. The proceedings could not be made inexpensive under those circumstances, because if the property was valuable, and it was decided to take the litigation before a crossing sweeper, leading counsel would be taken down to persuade the crossing sweeper on both sides. And pretty fees they would charge for such an exploit. That was where the expense was incurred, and not in official fees. Such valuable property was in question that patentees provided themselves with the most expensive weapons for fighting their battles, and they could not be made less expensive. If a one hundred ton gun was required, a one hundred ton price had to be paid for it, no matter whether the gun were fired at savages or at ironclads. If circuitous proceedings were introduced and multiplied the expenses must be overwhelming. The next question had been so thoroughly discussed between extrremely able combatants that it was not necessary to refer to it at length. Sir Lloyd Wise had stated that he was impressed with the danger of rendering patent property uncertain, and Messrs. Carpmael and Kilburn had corroborated what he had said in that respect; but they had been well answered by other speakers. Most of Mr. Roberts's remarks he had already replied to, but there was one which he must mention, because it had not otherwise been referred to. Mr. Roberts stated that the case of the Edison lamp, which was instanced as a case of the hardship of imposing compulsory working on a patentee, came to nothing at all, because the filaments which had superseded the originally designed filaments were themselves infringements, and that to make those infringements, was to work the patent. It was really a question of what amounted to working. If it were said that anything which was an infringement amounted to working the original patent it was perfectly clear that a new system of chicanery would be introduced. As an illustration, Edison's original patent for the telephone included also the invention of the phonograph, two absolutely distinct things. Both of them were, however, new speaking machines, and could fairly be included in that general category, being made the subject of a single patent. Suppose in such a case the inventor said that he would take all the benefits of monopoly with regard to the telephone, but would support his monopoly by working the phonograph, how was that any improvement? The phonograph was a toy, practically speaking, but the telephone was one of the first necessities of business life. Was it to be contended that because the patentee chose to mix up the telephone and the phonograph in one patent, he was to have a most oppressive monopoly of the telephone, paying for it the price of free use and adequate manufacture of the phonograph. Such a case would not bear stating. If patents were necessarily simple things granted for an absolutely single invention which could not be identified with anything else, it might be possible for Mr. Roberts to maintain his point. But in view of the actual complexity of patented inventions, it was impossible to sustain the point which he had proposed that evening. The answer was that if it was to be said that the mere working of any infringement of Edison's patent supported that patent, one would simply be setting the patent agents upon new ways of driving their coaches and four through the Act of Parliament. Some exceedingly interesting comments had been made by Professor Boys, which dealt with a subject which he (the author) was not competent to treat of, but which he had no doubt would be carefully considered at the Patent Office and receive the attention they deserved. He had already dealt with Mr. Carpmael's points so far as they affected the paper, but that gentleman raised another point as to the effect of the convention. He could not help thinking that Mr. Carpmael's criticism on the convention was to a certain extent founded on a misunderstanding of the proposal, with which Mr. Levinstein and Sir Joseph Lawrence were particularly identified, and Mr. Carpmael had supposed the compulsory working which they were proposing to introduce to be of the nature of the compulsory working obtaining under the German and French laws. It had been made quite clear that that was not so. It was very difficult to discuss such a question in the dark, and he was not in the least surprised to hear Mr. Carpmael speaking to what was not in fact the proposal which had been submitted to the Board of Trade. In a sense it was quite right to deal with the German proposal, because they had not yet seen what the Board of Trade proposed, and they certainly had seen in certain newspaper articles a very wild, and probably an altogether unauthorised statement that the President of the Board of Trade proposed to introduce during the year an Act to assimilate the English system to the German system. He had no doubt, from what Mr. Levinstein had said, that that was

an altogether mistaken view of the proposals which the President of the Board of Trade had under consideration. But at any rate, it was made public, and Mr. Carpmael, in addressing his criticism to that, was justified in saying that in the uncertainty in which all at present stood as to the form in which the proposal would be submitted to Parliament, it was necessary that the defects of the German system should be exposed. Nobody present, however, proposed the German system, or suggested that it would be applicable to the case of this country. There was one point on which he found himself very much at issue with Mr. Iselin, who had said that the more modern view was that patents were granted, not for the protection of manufacture, but of invention. He could not help thinking that if at any stage of the discussion the great importance of practical value was lost sight of, they would land themselves in the clouds altogether. It might in a sense be true, that what the Patent-law considered was invention, but the only invention which it was worth while, from the point of view of the public, to protect, was one of practical utility which was capable of being reduced to a manufacture, He, therefore, thought that the point that Mr. Iselin had made against him (the author) was rather a verbal than a substantial one. He had dealt incidentally with the very interesting remarks that fell from Mr. Kilburn. He had said all he could properly say with regard to the charge Mr. Burdick brought against him of want of sympathy with the patentee. With regard to the question of the shortness of the period of the patent and the heaviness of the fees, if he had time he thought it would be easy to show that the English system was a good deal better in those respects than the American, which led to chicanery. He did not say that chicanery was always a bad thing, but generally it was. He doubted very much the value of that chicanery which enabled a patentee in America to extend his term for four years by dilatory correspondence with the Patent Office, and in that way to secure a monopoly which, if it were right he should have it, would be very much better given by an extension of the term.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to Mr. Gordon for his excellent paper, and the meeting terminated.

Mr. G. G. M. HARDINGHAM writes :—

Mr. Gordon's paper entitled "Patent Law Reform" is a most interesting one from an historical point of view; but I must confess to having felt some disappointment when I found that the only reform he proposed had reference to the section which authorises the Court "to make such order for an injunction as it may see fit." This is a provision, the legal effect of which Mr. Gordon is far better qualified to judge than I am; but having regard to the title of the paper, I had hoped to hear Mr. Gordon's opinions and suggestions upon many other subjects in respect of which our law obviously calls for improvement.

Mr. Gordon appears to give a qualified approval to the idea of rendering the working of patented inventions compulsory, although he admits that practical difficulties arise in the application of that principle. It strikes me as fortunate that difficulties are met with and objections found to the application of a remedy which would be a thousand times worse than the disease it is supposed to cure. One cannot but admire the persistence with which Mr. Levinstein has advocated his proposal, but it is some satisfaction to those who take a broad view of the manufacturing interests of this country, to observe that he has during the last few years considerably modified his demands.

There is still a great deal to do to place British patentees in the position which they ought to occupy if the manufacturing interests of this country be made the first consideration; but to place the proprietors of patents under an obligation to work their inventions whether there exists a demand for their products or not, is certainly not one of the measures likely to conduce to the attainment of the object in view.

From the point of view of public policy, the grant of a patent should be looked upon—not as a reward to an inventor, and still less as a tax upon him—but as an encouragement to him to introduce the invention, and thus to promote industry and trade. Keeping this object clearly in view, the patentee's position should be made as easy and as safe as possible. He should be subjected to no harassing conditions, particularly such as are of a perfectly futile character, as, for instance, the compulsory working of his invention. He should not be taxed beyond what is actually required for defraying the expenses of the Patent-office, and even as to that, it would probably pay the country better if the Patent-office made a loss, instead of a profit. A British patent, maintained for the full term, costs a patentee, in Government taxes alone, an average of £7 per annum. A United States patent costs, in Government taxes, 8s. 4d. per annum. Which has been of most benefit to the community at large? The eight shilling wise, or the seven pound foolish policy? It cannot for a moment be doubted that the United States policy is the right one, and that it has been of incalculable benefit in fostering the mechanical genius, and the manufacturing industry which directly results therefrom.

In the recently introduced examination system some attempt has been made to secure a little more respect for British patents as regards the novelty of the inventions claimed, but it is after all but a poor attempt; the examination prescribed by the Act being so limited in character, as to render the result, in numberless cases, utterly misleading. It is quite as common to find an invention anticipated by a United States specification as by a British specification, and yet the former are not included in the examination at all.

The British inventor is at another disadvantage by

reason of the term of his patent being limited to 14 years; this term being reckoned moreover from the date of the application for, as distinguished from that of the grant of, his patent. In Continental countries the term is from 15 to 20 years; in the United States 17 years; and in Canada 18 years. Why should the British inventor be handicapped in this manner as compared with foreign inventors? I have for many years advocated a plan for the grant of letters patent whereby the term of provisional protection — if one must have one — is separate from, instead of being included in, the term for which the patent is granted, the latter running from the date of lodging the complete specification and applying for letters patent. This term ought, moreover, to be 16 or 17 years, in order to put British inventors on a par with foreign inventors.

These are a few of the points in respect of which our Patent-law calls for reform. There are others, but I have already occupied sufficient of your time.

DECLINE OF THE CHINA TEA TRADE.

China held the tea trade of the world from 1678, when tea was first introduced into England in a small way, until 1837, when tea from India appeared as a rival. The total exports of tea from China reached their highest point in 1886, according to the American Consul at Foochow, when the amount reached 300,000,000 pounds. From that time to the present, a gradual decline is to be noted. In 1884 the tea consumption of the non-tea producing countries of the world was 372,000,000 pounds. Of this amount China furnished about 72 per cent., India and Ceylon 18 per cent., and Japan and Formosa about 10 per cent. During the succeeding twenty years the world's consumption almost doubled. Of the 644,000,000 pounds consumed in 1904, however, India and Ceylon contributed 60 per cent., China 30 per cent., and Japan and Formosa 10 per cent. The important British market, which in 1860 took 78,000,000 pounds of Chinese tea, began at that time to use the India and Ceylon product appreciably. In 1905 the British tea consumption was 260,000,000 pounds, or 6 per capita, of which China supplied about 2½ per cent., the enormous Indian and Ceylon increase having practically driven Chinese teas out of the market. The same is true in Australasia, where the per capita consumption has now reached the high mark of 8 pounds per annum. In 1895, Australasian tea purchases were 36,000,000 pounds, China supplying less than 2 per cent. China's tea trade with Russia is the only phase that has shown a steady, healthful growth. In 1899 Russia took 132,000,000 pounds of China tea, or over one-half of the total exported. Even there the India and Ceylon tea merchants are trying to obtain a strong foothold. The Russian peasant wants a cheap tea, and if Indian exporters can reach this class they will establish themselves in the Russian market. The per capita consumption of the United States in 1905 was about the same as fifty years ago, namely 1·3 pounds per annum, the increased population accounting for the increased imports, which last year amounted to 103,000,000 pounds. Up to 1865 China supplied all of the tea consumption in the American market, but in 1905 only 40·3 per cent., while Japan furnished 32 per cent., Formosa 17·2 per cent., and India and Ceylon 10½ per cent. The latter made its entry into the American markets in 1885, with sales of 2 per cent. of the total imports. Practically all Japanese teas go to America. It may be noted that India and Ceylon teas are competing very strongly with the Japan teas in the Canadian market, and it will be interesting to note the results of this competition. The Formosan tea trade with America shows a steadier and more healthful growth than that of any other country. The Formosa oolongs have entirely replaced the Amoy oolongs. Chinese teas are still popular in the United States on account of the small amount of tannin in the leaves. That the American tea market is capable of great development is not to be questioned. The American taste has been towards coffee, the consumption of this article having increased from 2·8 pounds per capita in 1830 to 11·8 pounds in 1899. Coffee drinking is more expensive than tea in America, according to the Consul, and proper methods of advertising China tea in America would very probably bring profitable results. The Imperial Maritime Chinese Customs have repeatedly criticised the careless native methods adopted in the growing and preparing of the leaf. It is contended that machine rolling is not adapted to the China leaf, but there is much that the country can do towards improving the methods. A visit to the once famous tea districts near Foochow shows that the tea plants are not cared for as they should be. They are not well pressed, and frequently the soil is over-taxed by the planting of potatoes and beans. Co-operation on the part of buyers might do much to prevent illicit practices on the part of the packers, and assist in keeping up the standard. The Consul adds, "While there is so much progress in establishing modern schools in China, there should be something done towards establishing agricultural schools, where the proper methods of cultivating the two staples, tea and silk, could be taught."

PANAMA TORTOISESHELL.

The hawk's bill turtle, or imbricated turtle, which furnishes the tortoiseshell of commerce, is found only in the Gulf of Mexico and Caribbean Sea. This turtle is recognised by the low, wide head, a long narrow mouth, the upper jaw prolonged, and hooked like the beak of a hawk. The shell is flattened and serrated behind with five vertebral and eight lateral plates overlapping one another like scales of a fish.

The colour is yellowish above, mottled with chestnut brown, and yellowish white below. Young turtles have a black spot on the four rear pairs of plates. Old turtles have a thin yellow plate on the belly, which is much sought after, and commands a higher price. This hawk's bill turtle feeds on seaweed, crabs, &c. According to the American Consul at Colon, the shells shipped from his district are taken from turtles caught on the Lagarto and San Blas coasts of the Caribbean Sea during the months of May, June, July and August, when they approach the shore to deposit eggs, which are laid on the sandy beaches above high water mark at night; holes are dug about one foot and a-half deep, and the eggs deposited therein; generally about three layings are made, during a period of nine weeks. The eggs are lightly covered with sand, and left to be hatched out by the heat of the sun. The turtles are caught either while on shore or in the water by means of nets. As a rule they are killed immediately after being caught, cleaned, and the shell-frame washed with sand. On the San Blas coast, however, the Indians do not kill them, but at once proceed to remove the shell by subjecting the turtles to great heat, afterwards throwing the turtles back into the sea. By the application of heat the successive plates of shell come off very easily. Turtles caught in these waters vary in size from one to to four and a half feet long, with a maximum weight of one hundred and fifty pounds, and the average weight of shell obtained from each is from six to seven pounds. The commercial value of tortoiseshell depends upon the thickness and size of the plates rather than upon the brilliancy of the colours. The price of shell in the Panama market fluctuates from 12s. 6d. to 25s. per pound. As the best prices are obtained in England, the largest amount of shell shipped from Panama comes to this country. The San Blas Indians, however, sell a large amount of shell to coasting steamers. During the year 1905, the total amount of tortoiseshell shipped from Colon to all countries was estimated at 16,000 pounds.

THE BELGIAN TANNING INDUSTRY.

The tanning industry of Belgium is now one of considerable importance. Not only do the Belgians work the native skins, but they import about fifty tons annually. Belgium contributes annually to this industry about 800,000 skins, which include ox, horse, buffalo, kid, and sheep skins, and the imports are chiefly from Argentina, Uruguay, Brazil, France, Holland, and Germany. Australia and South America send in sheepskins tanned, as well as fleeces, which are clipped after arrival. For several years past chrome has been used for tanning with considerable success. The large hides are tanned with oak bark, or the extracts of oak, quebracho, &c. Kid and sheep skins intended for fine work are treated with sumach; those for chamois leather work are treated with fish oil; while dressed hides are tanned with alum and salt mixed with the yolks of eggs and flour. The materials for fine tanning work are produced in Belgium, such as oak bark and certain extracts. Most of the materials required are, however, imported. Sole leather is manufactured throughout Belgium, but the leading centres are Stavelot, St. Hubert, Laroche, Namur, Peruwelz, and Soignes. Strap leather is manufactured in Liège, Verviers, Herve, and other places adjoining. Skins for gloves are tanned at various places throughout the kingdom. About sixty establishments are employed in the dressing and dyeing of skins. The importation of hides into Belgium in 1905 was valued at over £4,000,000, of which amount, those to the value of £3,600,000 were for Belgium use, the balance passing to other countries. The exports in the same year amounted to £3,200,000, of which £2,700,000 worth was from Belgium, the balance passing through from other sources.

SCHOOL HYGIENE.

The second International Congress on School Hygiene will be held in the University of London Imperial Institute City Technical College, South Kensington, from August 5th to 10th, 1907, under the presidency of Sir Lauder Brunton, LL.D., M.D., V.-P.R.S. The first Congress was held at Nuremberg in Easter week, 1904. It was attended by about fifteen hundred delegates representing almost every civilised State. The influence of this Congress has already made itself felt in many countries in the literature, laws and regulations connected with health and education.

The following is a list of the special sections formed at the Nuremberg Congress, which will also, subject to any modifications that may appear desirable, be those into which the work of the London Congress will be divided:—

1. The physiology and psychology of educational methods and work.
2. Medical and hygienic inspection in school.
3. The hygiene of the teaching profession.
4. Instruction in hygiene for teachers and scholars.
5. Physical education and training in personal hygiene.
6. Out of school hygiene, holiday camps and schools. The relations of the home and the school.
7. Contagious diseases, ill-health, and other conditions affecting attendance.
8. Special schools, including those for feeble-minded and exceptional children.
9. Special schools for blind, deaf, dumb, crippled and invalid.
10. Hygiene of residential schools.
11. The scaool building and its equipment.

ARTS AND CRAFTS.

Glass.—It is with a feeling of distinct relief that, at this time of year in particular, we turn away from the shop windows, which have been filled to overflowing for the last couple of months with "Christmas Presents and New Year Gifts," and goods at "Lowest Sale Prices" (in other words, with articles which it is fondly hoped look worth more than the money paid for them), and direct our attention to the exhibitions of artist-crartsmen, or of firms who have some care for art and craftsmanship, at the smaller galleries. Not that good workmanship, or even good art, is never to be found in the shops; indeed, it would be saying little for the Arts and Crafts movement as a whole, to suggest that it had no really direct influence on the ordinary commerce of the country. Still, it must be admitted that, at any rate during the months of December and January, what is good is mixed up with so much that is bad, that to search for it is not unlike looking for the proverbial needle in the bundle of hay. This is very markedly the case with glass. There is something very attractive at first sight in the brilliant hues and the bright and rather glittering colours of much of the cheap imported glass which is displayed for sale now-a-days. Its opalescence and its gorgeousness of colour do indeed *sautent aux yeux*. But after a while the aggressiveness of the colour, its rather metallic quality, and a certain subtle lack of refinement begin to tell, and it is with a sense of restfulness and of relief that we look at the delicate and graceful work which is being done by the Whitefriars Glass Works. Nothing could be further removed from loudness, or from any desire to be conspicuous at all costs than the delicate colouring, the restraint—both in the shapes of the blown vases and in the use of cutting—which characterise Messrs. Powell's work. Amongst the objects recently shown at the Fine Art Society there is not quite so much cut glass as might have been expected from the exhibit last year at the Arts and Crafts. What there was, however, shows that the makers are still in the main working on the same lines, and decorating fairly thin bowls and vases with slight cutting—and with very good results. The one piece of more heavily cut glass, a copy of an eighteenth century Waterford bowl, is interesting as representing a phase of cutting which, though much more elaborate than the early Roman and other work imitated before, is yet a long way off the facetted surfaces of a still later period. The latest blown vases include reproductions of old forms, both from old vases and from pictures by masters like Van der Velde and Ghirlandajo, adaptations of ancient designs, and copies of earthenware and other shapes in glass. Two or three pieces from South American models are decidedly unusual. These examples, together with a copy of the Mount Carmel vase at the Dublin Museum, serve to indicate the wide range from which the copies and adaptations of old work have been gathered. In the Minoan Lily vase, adapted naturally from a discovery at Crete, and in several other pieces, we have examples of delicate engraving on glass. The collection also included vases decorated with elongated "prunts" and thin threads of delicately coloured blue, or purple, or white glass—and a certain number of vessels mounted in silver. This metal, by the way, seems far more in keeping both with the colour and the form of this fragile-looking blown glass than the iron which was used with it some years back—which always seemed too heavy and clumsy for the material it framed.

Pottery.—Lustre has for some time past been a powerful magnet to potters, and it is towards lustre that, so far as their pottery is concerned, the Pilkington Tile and Pottery Company have been turning their attention of late. Lustre has, of course, been with us now for a good number of years. The process, after being apparently lost or disregarded for centuries, reappeared in our own time in the latter half of the nineteenth century. Everyone with any pretentions to knowledge is familiar with the work of Mr. de Morgan in this country, if not with that produced on the Continent by Cantagalli, Clément Massier, Szolnay, and others. The earlier attempts at lustre, however, were mainly either efforts to obtain iridescent colour, simply as colour, or aimed rather at reproducing or re-introducing the effects already familiar in Persian, Hispano-Moresqne, or Italian majolica work. Of late years, however, potters have been experimenting largely in the direction of glazes, in fact, it may be fairly said that modern advance in the matter of artistic pottery has been mainly in the introduction of new glazes, through the increase of chemical knowledge. Some of these, of course, are revivals of glazes apparently long since lost or only known in the East—but by far the greater number are new—composed either of ingredients unknown to the old master potters, or of known ingredients in hitherto unknown combinations. It is thus that the modern potter has a chance of producing effects in lustre such as it has never before been possible to obtain; for his choice of background colour instead of being rigidly restricted is almost unlimited. Previous exhibitions of Messrs. Pilkington's Lancastrian pottery have shown us how varied and how perfect are the glazes which Mr. Burton has produced for the decoration of his ware. The latest show of his work at the Fine Art Society has proved that on many of these glazes he can get fine iridescent and lustrous colour—which means, of course, that he can obtain a great number of quite new effects. Unlike the work shown last year at the Arts and Crafts, the pieces in the recent exhibit are almost all of them painted—sometimes with set patterns but more often with conventional designs or figure subjects painted straight off on to the pieces they decorate. If this is only the beginning of what modern lustre may attain to, there seems every prospect of achieving in this "commercial" and "inartistic" twentieth century something which we may justly look upon as an artistic triumph.

OBITUARY.

THOMAS R. DALLMEYER.—Mr. T. R. Dallmeyer died on Christmas-day last, after a short illness. Mr. Dallmeyer, who was born in 1859, became a Member of the Society of Arts in 1887. In 1893 he read a paper on Telephotography, for which he received the Society's medal. Mr. Dallmeyer's father—Mr. J. H. Dallmeyer, who married a daughter of Andrew Ross, the well-known optician —was the founder of the firm which bears his name, and which was carried on by him until 1884, when shortly before his death he resigned it to his son. Mr. J. H. Dallmeyer was one of the first opticians to turn his attention to photographic lenses, in the production of which he made many important improvements. His son carried on the business on the same lines, and himself introduced several novel forms of lenses, the most important of which was the telephotographic lens, first made in 1891. Mr. Dallmeyer was an active member of the Royal Photographic Society, and its President from 1900 to 1903.

HON. SIR JAMES FRANCIS GARRICK, K.C.M.G., K.C.—Sir James Garrick, who was a member of the Society of Arts since 1886, died at his London house on Saturday, 12th inst. He was born at Sydney in 1836, and early in life he became a partner of the late Chief Justice and Premier of Queensland, Sir Charles Lilley, as a solicitor at Brisbane. He was called to the English Bar in 1873, and shortly afterwards returned to Queensland. He held the office of Crown Prosecutor from 1874 to 1877, Attorney-General for Queensland in 1878 and 1879, and Post-master-General 1884. In the latter year he was appointed Agent-General in London for Queensland, which office he held until 1888. In 1890 he was re-appointed and continued as Agent-General until 1895. Sir James was a member of the governing body of the Imperial Institute, and director of several companies.

GENERAL NOTES.

THE CONSUMPTION OF TEA.—Figures given by Messrs. Gow, Wilson and Stanton in their annual review of the tea trade show that the reduction of the duty on tea from 6d. to 5d. has had an immediate and considerable effect upon the consumption of tea in the United Kingdom, which for 1906 was 10,345,233 lbs. ahead of 1905. During the ten years from 1890 to 1899, when the duty stood at 4d. per lb., there was an average increase in the consumption of nearly 5,000,000 lbs. per annum. This expansion ceased so soon as the 6d. duty was felt, and it was not until last year that any appreciable advance took place. It has been contended by experts that "saturation point" has been reached as regards the use of tea in this country. At 6 lbs. *per capita* the consumption is higher than in most countries, but the figures for 1906 show that the maximum consumption has not been reached. Were the duty lowered to the old figure of 4d., or lower, it is probable that the consumption would show a substantial increase. A feature of the past year was the use of a better class of tea, and consequent neglect of poorer kinds.

SANTA CATHARINA.—Little is heard of this island and state of Brazil, but it may be gathered from Mr. Vice-Consul Chaplin's report upon it (Cd. 2,682), that it is a thriving little place. The population of the capital is about 13,000, and of the whole island 33,000. It is about the size of Barbados, very healthy and suitable for the cultivation of coffee, bananas, onions, mandioca, manicoba, rice, cotton (of good quality), oranges, beans, potatoes, and in fact every kind of agricultural produce. It is a little hot in the summer, when the temperature varies from 78° to 99° Fahr. in the shade, but in the winter it ranges from 80° to 50°. The island is well situated for the exportation of its products to the great consuming markets of Santos, Rio de Janeiro, and the River Plate. Steamers drawing up to 13½ feet can enter the town anchorage, and those drawing more can anchor about five miles from the town in the North bay, in the good anchorage off Ratones island.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

JANUARY 23.—"The Panama Canal—the 'Lock Canal' type and the 'Straits of Panama' type." By PHILIPPE BUNAU-VARILLA, formerly Chief Engineer of the Panama Canal Company. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

JANUARY 30.— "Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 24.—"The Bhils of Western India." By CAPTAIN E. BARNES, Indian Political Department. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

FEBRUARY 14.—"The Practical Side of Famine in India." By SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces.

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

FEBRUARY 19.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

LECTURE I.—JANUARY 28.—*Alluvial Gold Mining.*—Small scale methods and manual appliances—Hydraulic sluicing — Gold dredges; chief types; ground to which suitable; costs—The deep leads of Australia; their nature; distribution; methods of discovery and mining.

LECTURE II.—FEBRUARY 4.—*Lode Mining.*—The term "reef" used both for ore and "country" rock—The chief types of gold-bearing lodes—The importance of ore genesis in reference to mine development—The chief gold fields of the world and their structures—The Rand and its banket.

LECTURE III.—FEBRUARY 11.—*Gold Production.*—The crushing of the ore; the stamp mill—The extraction of gold by amalgamation; smelting; chlorination and cyanidation—Reforms in consequence of the tube mill and the filter press—Tube mill *versus* pan—Proposed abolition of the stamp battery—The depth of ores; surface and secondary enrichment—Mining costs and gold mining organization.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.
February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.
April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 21...British Architects, 9, Conduit-street, W., 8 p.m. Sir L. Alma-Tadema and Mr. W. Brindley, "Marbles: their Ancient and Modern Applications."
Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Rev. Canon Girdlestone, "The Scriptural Idea of Miracles."
London Institution, Finsbury-circus, E.C., 5 p.m. Mr. C. Harrison Townsend, "The Art of Pictorial Mosaic."

TUESDAY, JAN. 22...Royal Institution, Albemarle-street, W., 3 p.m.
Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. James Tayler Milton, "Internal Combustion Engines for Marine Purposes."
Anthropological, 3, Hanover-square, W., 8½ p.m. Annual Meeting.

WEDNESDAY, JAN. 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Philippe Bunau-Varilla, "The Panama Canal—The 'Lock Canal' type and the 'Straits of Panama' type."
Geological, Burlington-house, W., 8 p.m.
United Service Institution, Whitehall, S.W., 3 p.m. Mr. A. H. Cheatle, "Gun Deafness."
Entomological, 11, Chandos-street, W., 8 p.m. Annual Meeting.
Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

THURSDAY, JAN. 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Capt. E. Barnes, "The Bhils of Western India."
Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 6 p.m. Dr. Edmund Gosse, "The Novels of Benjamin Disraeli."
Royal Institution, Albemarle-street, W., 3 p.m.
Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Clifford C. Paterson, "Investigation on Light Standards and the Present Condition of the High-Voltage Glow Lamp."

FRIDAY, JAN. 25...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. C. A. Ablett, "Alternating-Current Commutator Motors."
North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Clinical, 20, Hanover-square, W., 8½ p.m.
Physical, Physics Laboratory of the Royal College of Science, Imperial Institute-road, South Kensington, S.W., 5 p.m. 1. Mr. W. A. Scoble, "The Strength and Behaviour of Brittle Materials under Combined Stress." 2. Mr. F. Twyman, "A Spectrophotometer." 3. Mr. K. J. Tarrant, "Photographs of Electric Sparks."

SATURDAY, JAN. 26...North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m. (Graduate Section.) Paper by Mr. W. J. Sedcote.

Journal of the Society of Arts.

No. 2,827. VOL. LV.

FRIDAY, JANUARY 25, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 28, 8 p.m. (Cantor Lecture.) PROFESSOR JOHN WALTER GREGORY, D.Sc., F.R.S., "Gold Mining and Gold Production." (Lecture I.)

TUESDAY, JANUARY 29, 8 p.m. (Applied Art Section.) WILLIAM DALE, F.S.A., "Artistic Treatment of the Exterior of the Pianoforte."

WEDNESDAY, JANUARY 30, 8 p.m. (Ordinary Meeting.) JAMES PARSONS, M.A., "Apprenticeship."

Further details of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, January 24; SIR WILLIAM LEE-WARNER, K.C.S.I., Vice-President of the Society, in the chair. The paper, "The Bhils of Western India," by CAPTAIN E. BARNES, was read by H. M. BIRDWOOD, C.S.I., LL.D.

The paper and report of the discussion will be published in a future number of the *Journal*.

VIVA VOCE EXAMINATIONS IN MODERN LANGUAGES.

The following is a complete list of the *Vivâ Voce* Examinations held during 1906:—

Place of Examination.	Date.	Number of Candidates.	Passed with Distinction.	Passed.	Failed.
French:—					
Acton and Chiswick Polytechnic	March 13.	39	3	28	8
Crouch-end Council School	March 14.	50	3	36	11
Willesden Polytechnic	March 15.	24	1	18	5
Manchester Education Committee	May 21.	21	5	10	6
Regent-street Polytechnic (Candidates from London Polytechnics)	June 7.	39	6	26	7
Kensington College (Candidates from London Polytechnics)	June 8.	43	5	26	12
"Barnsbury Park" L.C.C. School	July 2.	41	5	31	5
"Hugh Myddelton" L.C.C. School, Clerkenwell	July 3.	20	2	13	5
L.C.C. Evening School, Sussex-road, Brixton	July 4.	34	4	24	6
L.C.C. Evening School, Queen's-road, Dalston	July 5.	21	5	14	2
L.C.C. Evening School, Plough-road, Clapham Junction	July 6.	28	6	15	7
Merchant Venturers' Technical College, Bristol	July 10 & 11.	94	4	59	31
German:—					
Willesden Polytechnic	March 29.	17	4	7	6
City of London College (Candidates from London Polytechnics)	June 12.	34	9	16	9
"Barnsbury Park" L.C.C. School	June 25.	24	0	8	7
L.C.C. Evening School, Sussex-road, Brixton	June 28.	12	2	5	5
L.C.C. Evening School Queen's-road, Dalston	June 29.	15	6	6	3
Merchant Venturers Technical College, Bristol	July 17.	38	3	19	16
Spanish:—					
Manchester Education Committee	May 23.	10	—	5	5
City of London College (Candidates from London Polytechnics)	June 11.	22	2	9	11
"Hugh Myddelton" L.C.C. School, Clerkenwell	June 28.	10	—	4	6
Italian:—					
Regent-street Polytechnic (Candidates from London Polytechnics	June 7.	8	—	6	2
		644	84	385	175

The Examiners were Mr. E. L. Naftel for French, Professor H. G. Atkins, M.A., for German, Professor Ramirez for Spanish, and Professor Luigi Ricci for Italian.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ARTIFICIAL FERTILISERS: THEIR NATURE AND FUNCTION.

By A. D. Hall, M.A.,
Director of the Rothamsted Experimental Station, Lawes Agricultural Trust.

Lecture V.—Delivered December 17th, 1906.

Coming now to the last division of my subject—the Potassic fertilisers—I have to deal with a class of manures which have only assumed their present importance comparatively recently, and even now are not employed by the ordinary farmer to anything like the extent he makes use of nitrogen and phosphoric acid compounds.

The fertilising properties of wood ashes, formerly the only source of potash compounds, have long been known, but the quantity available in a country like our own is trifling; it has only been with the opening up of the deposits in the Stassfurth district that the potash compounds have assumed any economic importance. There, under conditions analogous to our own rock salt deposits in Cheshire, have been laid down beds, not only of gypsum and rock salt, but associated with them other beds containing the sulphates and chlorides of potassium and magnesium. By suitable treatment of these deposits are obtained, for commercial purposes, potassium sulphate and chloride in various grades of purity, as well as a still more impure mixture of sulphates and chlorides, sold as "kainit," and containing 12-13 per cent. of potash. These commercial potash compounds are nearly all deliquescent, owing to the magnesium chloride which is always associated with them. For some crops and soils chlorides are harmful, but the bad effect can always be obviated by putting on the kainit or other compound in the winter, when the potassium is arrested by the soil while chlorine is washed out in the drainage water. Little loss of potash will result. Dr. Dyer's examination of the Broadbalk soils at Rothamsted shows that the greater part of the potash which has been applied as manure during the last fifty years and has not been removed in the crop still remains in the surface soil, though some has been washed down and caught in the second and even the third layer of nine inches, in a manner that was not seen in the case of phosphoric acid. The drainage waters again show but little potash removed even from the most highly manured plots.

I have already indicated in the first lecture that in some way potash is necessary to the process of assimilation, and that the manufacture of carbohydrate will not go on in its absence. Some experiments of Hellriegel and Wilfarth with barley illustrate this function of potash very clearly. They started a series of water cultures, in one of which the supply of nitrogen increased in successive jars from nothing to the full amount required for the plant, the other constituents were fully supplied in every jar. In a second series, the phosphoric acid supply was similarly varied, and in a third series the potash. As would be expected, in each series the amount of dry matter grown was roughly proportional to the supply of the constituent which was in defect. Further, when nitrogen or phosphoric acid was lacking the formation of grain was small, but, as far as might be, the grains produced were perfect; a larger number of grains, but not bigger ones being found as the supply of phosphoric acid increased. Hence the weight of a single grain was fairly constant whether there was much or little nitrogen and phosphoric acid. But when potash was lacking the individual grains were small and undeveloped, and the average weight of each corn increased with each addition of potash. In the absence of potash the assimilation process was at a standstill, hence the grains could not be filled with the starch which is their main constituent. The following Table shows the total dry matter, the percentage of grain, and the weight of a single corn in each experiment of the three series:—

TABLE XXII. — Growth of Barley with Increasing Amounts of Nitrogen, Phosphoric Acid, and Potash. (Hellriegel and Wilfarth).

Nitrogen Series—Other Constituents in Excess.

282	29·8	42·8	34

The Rothamsted results with barley are less striking because of the large amount of potash originally in the soil; it is only during the later years, as has already been explained, that any deficiency of potash has been manifest on the plots that do not receive this fertiliser. Still, as shown in the following Table, which gives average results for the fourteen years 1889-1902, the use of potash has increased both the weight per bushel and the weight of the individual corns:—

TABLE XXIII.—ROTHAMSTED BARLEY.
(14 years, 1889-1902.)

Plot.	Manuring.	Weight per Bushel.	Weight of 100 Grains.
		lb.	Grms.
1 A	Nitrogen only	52·3	4·03
2 A	Nitrogen and Phosphoric Acid	52·2	3·86
3 A	Nitrogen and Potash	53·3	4·14
4 A	Nitrogen, Phosphoric Acid, and Potash	53·8	4·21

The effect of potash manuring on the production of carbohydrate, in this case sugar, is most manifest on the mangel crop. In Table II. (p. 135) one instance has already been given; Table XXIV. shows the effect of potash when used in conjunction with dung and various original nitrogenous cross dressings.

TABLE XXIV.—ROTHAMSTED MANGELS.
(12 years, 1895-1906.)

Manufacturing.	No Potash.	+ Phosphates and Potash.
	Tons.	Tons.
Dung only	18·6	19·5
,, and nitrate of soda ..	27·7	26·8
,, and ammonium salts..	21·8	25·9
,, and rape cake........	24·9	28·6
Dung, rape cake and am. salts	24·2	29·9

Here it will be seen that potash increased the crop in every case except where nitrate of soda had been used as the nitrogenous cross dressing, in which case the soda liberates so much potash from the soil that specific application of potassic manures is unnecessary. An earlier series of experiments showed that phosphatic manures added to dung brought about no increase of crop, hence, when both phosphates and potash were used in the second series of trials the potash alone was effective.

This result was the more striking in that dung itself contains a large proportion of potash, yet the use of 14 tons of dung per acre year after year, beginning in 1856, was still unable to supply the mangel crop with all the potash it needed.

Another very striking effect of potash, which is most manifest when the fertiliser is applied to grass land carrying a mixed herbage, is the way it encourages the growth of all leguminous plants. On the Rothamsted grass land, which is mown for hay every year, one plot gets a complete mineral manure—phosphates and sulphates of potash, soda and magnesia; the adjoining plot receives the same phosphoric acid, magnesia and soda, but no potash. The following Table shows the comparative yield and the composition of the herbage by weight:—

TABLE XXV.—ROTHAMSTED HAY CROP, WITHOUT AND WITH POTASH.

Plot.	Manuring.	Dry hay. 1856 to 1902.	Dry hay. 1893 to 1902.	Composition of herbage in 1903. Grasses	Composition of herbage in 1903. Legu.	Composition of herbage in 1903. Weeds.
		Cwt.	Cwt.	%	%	%
7	Complete mineral manure	38·8	36·5	20·3	55·3	24·4
8	Ditto. without potash	28·1	21·6	28·8	22·1	49·1

On the plots receiving a mineral manure including potash, half the vegetation now consists of leguminous plants. Where nitrogen is applied and potash omitted, no leguminous plants are to be found.

On these grass plots another very striking effect of potash manuring is also manifest, which confirms on a large scale the experiment of Hellriegel and Wilfarth's already quoted. On the potash-starved plots the grasses fail to a large extent to develop any seed, so that the heads are soft and barren, presumably because of the deficiency in carbo-hydrate formation. For the same cause the straw, not only of the grasses, but on the similarly-manured wheat and barley plots, is always weak and brittle when potash is wanting. One of the most important effects of potash upon vegetable growth is to make the plant more resistant to the attacks of fungoid diseases. I have already explained how susceptible the use of excess of nitrogenous manures renders the mangels on certain of the Rothamsted plots to the attack of a leaf spot fungus—*Uromyces betar*. The attack is, however, much less severe on the plots receiving an abundant supply of potash; there the plant remains healthy even though the nitrogen is in excess. Just in the same way the wheat on the potash-starved plots is always subject to rust, even in a good season when very little is to be seen on the other plots normally manured. The grass also on potash-starved plots is attacked by various fungi, hence it may be taken as a general rule that crops which do not receive their full supply of potash will be correspondingly susceptible to disease.

It is not possible to say whether this is due to any specific alteration in the composition of the cell contents or to a general lack of vigour, but the latter is probable, because an excess of potash tends to prolong the vegetative growth of the plant and to delay maturity. Plants receiving potash are always a little the greener, especially late in the season, and this is not always an advantage, as may be seen from the fact that the barleys grown on the plots receiving potash at Rothamsted show a somewhat darker and less attractive colour than those grown without potash. That potash tends to prolong growth may also be inferred from the fact that its effect upon the yield is always most pronounced in dry seasons. Referring again to Table XX. (p. 226), it will be seen that in the dry season of 1893 the yield of barley (grown also with ammonia salts and superphosphate) was increased by a dressing of potash from 18·1 to 30·8 bushels per acre, whereas in the wet season of 1894 the increase was only from 34·9 to 41·4 bushels per acre.

The examples I have been giving to illustrate the specific action of potash must, however, be used with some caution as a guide to the manuring of crops under ordinary conditions of farming. They are all extreme cases, drawn from the later years of the Rothamsted experiments, when the exhaustion of the available potash in the soil has become very pronounced through the continuous cropping with the help of a manure containing all the other elements of fertility except potash. Except on special soils, and with the specially potash-loving crops, it is not usual to find in this country that the use of a dressing of potash salts has any visible effect on the yield, so large is the stock of potash in the soil, and so well is it conserved by the ordinary systems of cropping. On the lighter soils, the sands and the gravels, potash is most likely to be deficient, and the ill-effects arising from its absence are intensified by the dryness of these soils. Even on such soils, potash manures will rarely be found remunerative for cereal crops; for mangels and potatoes, and to a less extent for turnips, they are necessary, while grass land can hardly be maintained in a satisfactory character without potash at regular intervals. On the stronger soils, potash is a remunerative manure for mangels, and occasionally for land laid up for hay, but in general, the use of nitrate of soda as a source of nitrogen will liberate enough of the locked-up potash in the soil for the needs of the crop. These points are well illustrated in the Rothamsted experiments on wheat, where there is a series of four plots receiving similar dressings of nitrogen and phosphates, in one case without any addition, in the others, with sulphate of soda, sulphate of potash, and sulphate of magnesia respectively. The source of nitrogen being ammonium salts no assistance in liberating the soil potash was to be derived from that source, consequently even in the first decade of the experiments the crop which was without any alkaline salt gave a lower crop than the rest. For thirty years, however, the sulphates of soda and magnesia were as effective as sulphate of potash itself, because each of these salts attacks the reserves of potash in the soil and brings some of it into solution. This process, however, had proceeded so far that, after thirty years' time, a full supply of potash from the crop was no longer obtainable from

the soil, and the yield with sulphate of soda or magnesia began to fall decidedly below that afforded by sulphate of potash itself. That the action of the soda and magnesia consists in liberating potash may be seen from the analyses of the crops grown; the use of magnesium sulphate, for example, as a manure does not materially increase the percentage of magnesia in the ash, but it does raise the proportion of potash.

a basic substance; the phosphate of lime contained in bones and similar compounds, the sulphate of lime in gypsum, are both ineffective, because they are neutral salts already saturated with a fixed acid; superphosphate of lime, being acid, even increases the draft on what is generally called the lime in the soil. Only basic slag, basic superphosphate, and nitrate of soda, among the artificial fertilisers, are independent of a

TABLE XXVI.—ROTHAMSTED WHEAT. Yield of grain per acre, 10-year averages; and constituents removed per acre in whole crop, average 40 years—1852-91.

12	,, super., and sulph. soda	33·4	34·3	25·1	30·1	26·7	35·0	1·2	5·7
14	,, ,, and sulph. magnesia ..	33·5	34·4	26·4	31·1	25·0	36·8	0·8	6·4
13	,, ,, and sulph. potash	32·9	34·8	26·8	32·5	29·6	50·0	0·2	5·9
7	,, ,, and sulphates, potash, soda and magnesia	34·7	35·9	26·9	35·0	31·8	53·1	0·4	6·5

In the same way, it has already been shown that the omission of potash on the barley plots did not result in any diminution of yield for the first thirty years of the experiment, even when the nitrogenous manure was ammonia salts. The amount of potash contained in many of our soils is really enormous; for example, at Rothamsted the soil is a strong loam, approaching a clay, and it yields about 0·5 per cent. of potash when attacked by strong hydrochloric acid, but this is increased to more than 2 per cent. when the whole material is brought into solution with hydrofluoric acid. The true clays will be even richer in potash, and under cultivation a large proportion will become available by the action of weathering and of the carbon dioxide dissolved in the soil water. It may be concluded that on all except the lightest soils the requirements of the farm for potash manures will be met by an application of kainit for the mangel crop and an occasional dressing upon the grass land.

In the course of these lectures frequent mention has been made of the part played by the calcium carbonate, it should always be remembered that few of the artificial fertilisers can yield their full value unless there is a sufficiency of lime in the soil. It is not merely a compound of calcium that is necessary, but supply of calcium carbonate in the soil. The action of the soil calcium carbonate on the three constituents of fertilisers may be sumarised as follows:—Among the nitrogen compounds the presence of some free base is necessary to the nitrification of the ammonia compound which is formed with the clay in the soil, and if ammonia remains unchanged there is always loss of nitrogen by the action of fungi which seize upon the ammonia. Again, the decay of all the organic nitrogen compounds into forms available for the plant is chiefly brought about by bacteria, and it is necessary to maintain a neutral or very faintly alkaline reaction in the soil if these bacteria are to grow freely. The value of an application of lime in promoting the decay of organic nitrogen compounds is very strikingly seen on old pastures, gardens, or land which has been heavily manured for some time with organic manures. As regards the phosphatic manures, carbonate of lime in the soil is necessary to diminish the precipitation of phosphoric acid in the highly insoluble states of phosphates of iron and aluminium, compounds which are but slightly available for the plant. Calcium carbonate not only tends to decompose such compounds already present in the soil but prevents their formation in proportion to its own

abundance in the soil. Lastly, the presence of carbonate of lime not only liberates potash from its insoluble compounds already alluded to, but tends to prevent soluble potash salts applied as manure from passing into an unavailable condition.

How effective lime may be both in unlocking old reserves of manuring and in keeping fresh applications in an active condition may be seen from the following table, which shows the effect of 2,000 lbs. per acre of ground quick-lime applied to two of the Rothamsted grass plots in 1903 :—

TABLE XXVII.

LIME ON GRASS, ROTHAMSTED.

Year.	Plot 7.—Yield with mineral manures only.		Plot 9.—Yield with complete artificial manures.	
	Unlimed.	Limed.	Unlimed.	Limed.
	Cwt.	Cwt.	Cwt.	Cwt.
1903	49·5	51·9	50·1	60·5
1904	61·9	61·8	63·7	69·8
1905	44·3	47·2	36·9	52·2
1906	34·4	41·4	39·0	50·0

On plot 7 the lime has been used with phosphates and potash only; on plot 9 ammonia salts are also used, and the great increase of crop caused by the lime is doubtless also due to the oxidation of old nitrogenous residues of former crops, roots and stubble, accumulated in the surface soil.

In the short remaining time at my disposal I propose to touch briefly on one or two general questions connected with the use of artificial fertilisers. At the present time the annual consumption of all kinds amounts to about 1,250,000 tons per annum, whereas the area of land under crops and grass is about 47,670,000 acres in the United Kingdom, hence there is an average annual application of about ½ cwt. per acre over the cultivated area of the British Islands. A rough calculation, such as alone is possible, shows this total amount to contain about 43,000 tons of nitrogen, 152,000 tons of phosphoric acid, and over 5,000 tons of potash. The question for consideration is whether this average consumption can be profitably increased or not. It should not, however, be forgotten that among the methods of fertilising the land the consumption of imported feeding stuffs must also be taken into account; many farmers purchase little or no artificial manure, but by feeding extensively with purchased cake and corn they are constantly adding to the fertility of their holding. In 1905 the consumption of cattle foods in the United Kingdom was roughly as follows :—

		Million tons.
Maize, barley, peas, and other grain	..	3·5
Maize and other meals	..	0·5
Linseed, cotton, and other cakes ..	..	0·36
Linseed and other oil seeds ..	..	1·14
Offals, rice, meal, &c.	..	0·16

Making a total of 5·66 million tons.

Again, calculating approximately, in these food stuffs there are about 130,000 tons of nitrogen, 58,000 tons of phosphoric acid, and 45,000 tons of potash; about three times as much nitrogen, one-third as much phosphoric acid, and nine times as much potash as are contained in the fertilisers applied to the land in the same year. Before this material reaches the land about half of the nitrogen will have been either retained by the stock or wasted, but only about 10 per cent. need be deducted from the phosphoric acid and potash. Hence the imported fertility due to feeding stuffs is much greater than that due to fertilisers proper.

TABLE XXVIII.—CONSUMPTION OF MANURE AND FEEDING STUFFS IN THE UNITED KINGDOM.

	Tons.	Nitrogen.	Phosphoric acid.	Potash.
Manure	1,250,000	13,000	152,000	5,000
Feeding Stuffs	5,000,000	130,000	58,000	45,000

Of course there are no means of deciding to what extent these foods could be replaced by products grown at home by the aid of fertilisers, but the practical question often arises of how far it is profitable to fatten cattle merely with the object of making farmyard manure. There are many growers of valuable crops like hops or potatoes, consuming large quantities of manure, who fatten a lot of cattle or pigs every winter, not because any particular profit attaches to the live stock, but because they consider they need the dung the animals make. Unfortunately, farm book-keeping is rarely conducted in such a manner as will show the cost of such an operation, but I can put before you one case which gives the price of dung made in this fashion. In the yards 8 tons of cotton and 15 of linseed cake, 13½ qrs. of maize and 60 qrs. of oats, 69 tons of hay and 10 of mangels were fed to horses and fattening beasts; from this 460 tons of dung were made, and the average cost as it left the

yards was 6s. per ton. This cost was arrived at by charging the full price of the straw and the compensation values of the various foods consumed, which are based upon the composition of the feeding-stuffs and such as would be now allowed to the out-going tenant for food consumed during the last year of the tenancy. The 6s. per ton of dung is independent of any profit or loss attached to the sale of the fat live stock, it represents merely what the dung may be supposed to have cost. Even if the live stock repaid the cost of their initial cost, their food, attendance, and other incidental expenses, the dung would still have cost the farmer 6s. per ton. Only when a number of costs have been worked out in a similar way can the individual farmer ascertain whether it is possible for him to feed cattle at a profit in order to make dung; in my own opinion it is generally an unprofitable operation, and the farmer could get the required fertility more cheaply by the purchase of fertilisers, ploughing in an occasional green crop to maintain the humus and tilth of his soil.

The next question is whether the quantity of fertilisers employed by the British farmer can be profitably increased; can he obtain an adequate return if he increases his manure bill? Here it is necessary to take into account what is known as the law of diminishing returns. It has already been stated, for instance in treating of nitrogenous manures, that the yield increases *pari passu* with each addition of nitrogen. This is only partially true, holding for the first small additions of nitrogen, while there is still a deficiency of that element; later, however, the law of the minimum begins to operate, and the yield is limited by the amount of water available, or by some other factor which determines the extent of growth. The law of diminishing returns, which holds for many things besides manures, expresses the fact that the first addition of manure gives the largest increase, and that with each further addition there is a progressively lower increment to the yield; the falling off being little at first but growing rapidly, until at some point the increase ceases entirely, however much manure is put on. Some of the Rothamsted wheat plots illustrate this very clearly: there was a series of five plots all treated alike as regards the phosphates and potash, but which received respectively 0, 43, 86, 129, and 172 lbs. of nitrogen as ammonia salts. The following Table shows the yields:—

TABLE XXIX.—EXPERIMENTS ON WHEAT, BROADBALK FIELD.
Averages over 13 years (1852–1864).

Plot.	Manures per acre.	Dressed Grain.		Straw.		Returns.	
		Produce per acre.	Increase for each additional 43 lbs. N in manure.	Produce per acre.	Increase for each additional 43 lbs. N in manure.	Low prices. Grain, 24s. per qr. Straw, 20s. per ton.	High prices. Grain, 32s. per qr. Straw, 30s. per ton.
		Bushel.	Bushel.	Cwt.	Cwt.		
5	Minerals alone	18·3	—	16·6	—	72s.	98s.
6	ditto and 43 lbs. N as ammonia salts	28·6	10·3	27·1	10·5	113s.	155s.
7	ditto and 86 lbs. N as ammonia salts	37·1	8·5	38·1	11·0	149s.	206s.
8	ditto and 129 lbs. N as ammonia salts	39·0	1·9	42·7	4·6	160s.	220s.
16	ditto and 172 lbs. N as ammonia salts	39·5	0·5	46·6	3·9	165s.	228s.

The first addition of nitrogen produced an increase of 10·3 bushels of grain and 10·5 cwt. of straw, the second gave but little less, while the fourth addition of nitrogen only produced an increase of half a bushel of grain and 4 cwt. of straw. Clearly, if the grain and straw produced paid for the first addition of nitrogenous manure, it would not do so for the fourth addition, and the last half bushel of wheat and 4 cwt. of straw cost much more than it was worth. It is not therefore

certain that a farmer will make more profit by increasing his manure bill.

A further conclusion may also be drawn from the above table—the higher the prices the products fetch the greater the amount of manure that can be employed with profit, whereas, when prices fall, it becomes necessary to reduce the expenditure instead of increasing it to obtain a bigger crop. This may be made clear by a diagram showing the cost of growing the crops on each plot, taking a fixed figure of 80s. per acre as representing the rent and the cultivation, which is the same on all the plots, and adding 30s. for each increment of nitrogenous manure. Thus we get a straight line representing the increasing cost of production with each increase of manure. For the returns two similar curves may be plotted, one showing the values of the crops when prices are low—corn at 24s. per quarter and straw at 20s. per ton—and the other for corn at 32s. per quarter and straw at 30s. per ton. It will be then seen that with the lower prices the crops ceased to be profitable before the third addition of manure is made; the second addition was most profitable, for the extra 30s. expended on manure produced an increased return of 36s. in the crop. At the higher scale of prices the crop was profitable even with the highest amount of manure, but the third application only returned 14s., and the fourth only 8s. for the expenditure each time of 30s. for manure. Generalising from this instance we see the truth of the dictum of the late Sir John Lawes, that low prices cannot be met by high farming, but only by a reduction in the expenditure. Such arguments, however, which tend to show that a farmer may pay too dearly for an extra amount of manure on his land do not apply to the question of using the manure with greater skill. Small as the application of fertilisers is per acre in the British islands, anyone having much experience of farmers will know that a good deal of it is wasted, because it is used either for the wrong crops or on unsuitable soils. The special manurial requirements of our standard farm crops, and the adjustment of the various fertilisers to the chief types of soil have been already so far worked out that a great amount of the waste now going on might be at once avoided. Indeed, if the half hundredweight of artificial fertiliser that is now used per acre of cultivated land in the British Islands were only applied with due knowledge the increased profit would more than justify the purchase of double the amount of fertiliser. An increased manure bill must be accompanied by an increased knowledge on the part of the farmer, just as it is pretty certain that the great jump which has been seen in the consumption of phosphates during the last year or two represents one of the first fruits of the movement for agricultural education throughout the country which began some twelve years ago. What provision, however, is the country making for adding to the stock of knowledge at the service of the farmer? A start has indeed been made in the direction of education, but the necessary preliminary to education is research. The teacher can only hand on what is already known, and I shall have accomplished my purpose in these lectures very imperfectly if I have not made you realise how much there is yet unknown about the growth of our commonest crops and the action of our standard fertilisers. Only by continued investigation and experiment can a knowledge be obtained of the conditions necessary to make the maximum profit out of our land, our crops, and our stock. What provision then is the country making for research in agricultural matters? Well, I can only tell you that the grants of our Board of Agriculture for agricultural research during the past year amounted to £425, while the corresponding grant in the United States of America (salaries and administration expenses being excluded in either case) was more than £200,000. It is true that in both countries the local authorities also spend some money on agricultural experiments, but the same disproportion would probably be found between the respective amounts, if the figures could be arrived at.

Are we to take it then that these figures represent the relative importance of the agriculture of the two countries, or does the larger figure indicate the greater need of the American farmer for experiment and investigation? The exact contrary is the case; in the British Isles we have to farm with dear land, dear labour, and a number of charges due to the proximity of a high civilisation. Farming in consequence can only pay when there is a considerable monetary return per acre, and the bigger yield that is required involves intensive cultivation, the purchase of fertilisers and the employment of skill, to a degree, is needless to our competitors on a virgin soil. But each increase in the expenditure and skill necessary to obtain a crop means a greater opening for knowledge and investigation; science can do little to save money for the man who merely

stirs the surface of a virgin prairie, scattering in the seed meanwhile, and then leaves it to take its chance until harvest. Compare the highly technical routine of the hop grower who spends £50 per acre before he harvests his crop, his repeated cultivations, his manurings, his sprayings for various ends; it is with this kind of crop that science can find its most profitable employment.

Looking at the average yields of the various countries of the world we find that Great Britain is the most intensively farmed country; it obtains the biggest crops per acre, it has to spend the most to obtain them. Furthermore, the bigger the crop the greater are the risks of disease and blight, and the greater are the difficulties in securing high quality. Here then in Great Britain exists the greatest need for knowledge and investigation; nor can we always beg knowledge from wiser countries, for many of our problems are special and brought about by the very conditions of high farming which prevail here. England was the first country to start an experimental station, yet Rothamsted still remains the only institution solely devoted to agricultural research in the British Isles, if we except the farm of the Royal Agricultural Society at Woburn. The income of the Rothamsted Station, derived from private benefaction, is about £2,600 a year; in the United States each of the 53 States possesses a station receiving £3,000 a year from the Federal Government, in addition to what the State itself may contribute, while there is also the great Central Department of Agriculture, of which I have already spoken. Yet Rothamsted cannot obtain a grant from the Board of Agriculture to extend its operations; the country is too poor, agriculture too unimportant an industry.

I have wandered a little perhaps from the text of these lectures, but I have done so with a purpose; the use of artificial fertilisers is bound up with research, and Rothamsted has done so much for their investigation in the past that I may be pardoned in pleading for its consideration in the work that still remains to be done. And that consideration can only be secured by public opinion; in this country the Board of Agriculture is not expected to give a lead, but it will provide what public opinion may demand, hence I feel justified in asking for the support of a great learned body like the Society of Arts in the appeal we are making, not only for the needs of our own institution, but for agricultural research at large.

SEVENTH ORDINARY MEETING.

Wednesday, January 23, 1907; Sir JOHN WOLFE-BARRY, K.C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bancroft, Augustus Charles, J.P., F.S.I., Stokes-hall, Plantain-garden River P.O., Jamaica, British West Indies.

Cooper, Hon. Francis Alfred, C.M.G., M.Inst.C.E., Director of Public Works, Colombo, Ceylon.

Freehill, Colonel Francis Bede, M.A., Martin-place, Sydney, New South Wales, Australia.

Gordon, Walter, P.O. Box 96, Harrismith, Orange River Colony, South Africa.

Ikébé, Kichitaro, The Tokyo Asahi Shimbun, 4, Takiyama-cho, Kyobashi-ku, Tokyo, Japan.

Rich, William, Trevu, Camborne, Cornwall.

Smith, Milton W., 413, Failing-building, Portland, Oregon, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Baltischwiler, E., Hotel Central, Zurich, Switzerland.

Chambers, Alexander George, 8, Khersonskaja, Onlitsa, St. Petersburg, Russia.

Hobsbaum, Isaac Berkwood, F.C.S., 79, Claremont-road, Forest-gate, E.

Ijuin, Admiral Goro, I.J.N., The Admiralty, Tokio, Japan.

Kerr, George A., Lynchburg, Virginia, U.S.A.

Newman, Arthur D., Messrs. Fraser and Chalmers, Limited, P.O. Box 619, Johannesburg, Transvaal, South Africa.

Trimmer, Lieut.-Col. Augustus Richard, Parkstone, Beckenham, Kent.

Walker, Captain Herbert Marriott, 228, Mackenzie-road, Beckenham, Kent.

Wyllie, Lieut.-Col. Sir William H. Curzon, K.C.I.E. M.V.O., 10, Onslow-square, S.W.

The paper read was—

THE PANAMA CANAL—THE "LOCK CANAL" TYPE AND THE "STRAITS OF PANAMA" TYPE.

By PHILIPPE BUNAU-VARILLA.

PART I.

THE SYSTEM OF CONSTRUCTION OF THE STRAITS.

When Charles V., in 1523, sent from Valladolid to Fernando Cortez the order to search out carefully on the east and west coasts of the New Spain the solution of the "Secret of the Straits" (*el Secreto del Estrecho*), he

opened up the great question which has been pending before humanity until our time. I hope to have the honour of making it evident to your minds: first, that this great secret is now discovered; secondly, that its principles were found about the year 1887, during the period when the old Panama Canal Company was at work; and thirdly, that science possessing henceforth all the solutions and all the practical elements necessary, the realization of veritable "Straits" between the Atlantic and the Pacific will take place, and that the work now being carried on by the Americans is only the preliminary phase of this great undertaking.

This secret that Fernando Cortez and his successors believed they would find in a line of fracture concealed between the two continental masses, resided in reality, not in the natural geography, but in the natural topography and hydraulics of the American Isthmus; not in disposition of its ground alone, but in the disposition of its waters and of its ground. Nature has certainly united the two continents together, but it has provided the connection with a hydraulic power such as it is only necessary to harness properly to allow it to displace the mass which obstructs the communication between the oceans, and to transport this mass into spaces which appear to be reserved and ready to receive it.

Definition of the "Straits."—Let us first give a few definitions so that our mind may be clear on this subject. What are we to understand by "Straits of Panama"? How does this new conception of the inter-oceanic water-way differ from the sea-level canal, the construction of which was undertaken in 1881 by Mr. de Lesseps, or from the sea-level canal as it was conceived by the American Government and the Isthmian Canal Commission, and submitted by that last body to the International Board of Consulting Engineers assembled in September 1905 by President Roosevelt at Washington?

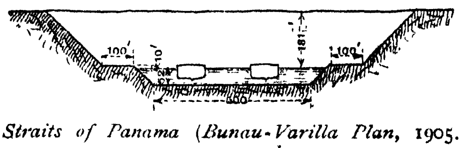
The sea-level canal of M. de Lesseps and that of the Isthmian Canal Commission were both canals with an invariable level, communicating freely with the Atlantic (the tides of which at Colon are insignificant—30 centimetres, or about 1 foot) and closed on the Pacific by locks. These locks prevent the Pacific tides (which attain 3 metres, or 10 feet) from penetrating into the canal, and from producing therein currents which might interfere with navigation. These two projects of a sea-level canal are similarly disposed in plan; the dimensions of their cross section only differ.

M. de Lesseps' sea-level canal had 9 metres (29½ feet) depth of water, 22 metres ($72\frac{1}{10}$ feet) width at the bottom, and 40 metres (131 feet) width at the water line.

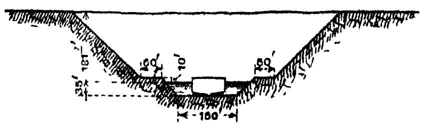
The sea-level canal of the Isthmian Canal Commission had 35 feet (10·67 metres) depth of water, 150 feet (45·75 metres) width at the bottom, and 220 feet (67·10 metres) width at the water line.

The water-way which I called the "Straits of Panama" when I submitted it to the Consulting Board in September 1905, is free of all locks. It communicates freely with the Atlantic and the Pacific. It is 500 feet (152·50 metres) wide at the bottom; 45 feet (13·75 metres) deep at the lowest tides, and its average breadth is 600 feet (183 metres) at the water line. It may be said, in round figures, that this new water-way would be three times broader and one-fourth deeper than the widest and deepest canal ever conceived across the Isthmus of Panama. It may also be said that its breadth, which is about equal to that of the Thames at London-bridge at low tide, is three times less than that of the Bosphorus at Hussein Pacha and at Kawak.

It is a water-way, the dimensions of which are exactly intermediary between those of a natural Straits like the Bosphorus and those of the widest artificial roads planned. It is a water-way of a width similar to those of the great navigable rivers. Strictly speaking one has the right to call such a water-way "Straits" as well as "Canal." (See explanatory note of Fig. J. in appendix, page 273.)



Straits of Panama (Bunau-Varilla Plan, 1905.)



Sea Level Canal (Isthmian Commission's Plan, 1905.)

FIG. J.—COMPARATIVE CROSS SECTIONS.

I selected the first appellation in order to characterise the suppression of all artificial work, such as tide locks, with which the plans of the Panama sea-level canals have always been encumbered, and in order also to charac-

terise the absolute liberty of navigation and of crossing which the ships will enjoy. Because of the great width and of the great depth given to the "Straits of Panama," it deserves an appellation which recalls the natural not the artificial navigable channels.

Tidal Currents and Currents of Fluvial Water in the "Straits of Panama."—At the simple announcement of a free inter-oceanic communication a preliminary question rises in all minds. Is it possible? Is there not a difference of level between the oceans which makes irrealisable such an open communication? My immediate reply is: No, there is no appreciable difference between the average level of the two oceans, but, as I have already said, the Pacific at Panama has tides which make it rise 3 metres (10 feet) and cause it to descend 3 metres below the average level. On the other hand, the Atlantic at Colon has no tides worth mentioning. Variations of level from 30 centimetres (1 foot) above or below the average level—that is all that has been observed. This being laid down another question arises which has often been answered carelessly in the negative. Will not the periodical variations of level of the Pacific cause currents in the canal incompatible with navigation?

The same question was raised about Suez a long time ago. The Red Sea at Suez has tides like the Pacific, but about one-third the amplitude of the Pacific tides. At a distance from the Red Sea equal to about also one-third of the distance between the Pacific and the Atlantic is a vast surface of water—the Bitter Lakes. They have an almost invariable level like the Atlantic. On the Suez Canal, therefore, the same conditions which are found at Panama are reproduced on a scale of one-third.

In 1856, Lieussou, a member of the Naval Hydrographic Engineers Corps of France, calculated that the maximum of the flood current between the Red Sea and the Bitter Lakes would be 1·16 metre per second and the maximum of the ebb current would be 0·97 metre per second. This calculation, formulated thirteen years before the inauguration of the Suez Canal, was almost rigorously confirmed by experience. After many years it was established that the maximum flood current was 1·20 metre per second, and the maximum ebb current, was 1·1 metre per second. Between theory and experience there was, therefore, only a difference of eight hundredths of one knot for the flood and twenty-five hundredths of one knot for the ebb currents. This proves what degree of confidence we may have in such calculations.

The slope between the Atlantic and the Pacific at high or low tide being about the same as between the Bitter Lakes and the Red Sea at high or low tide, the tidal currents must be about the same in the two cases. A Commission of the Academy of Sciences of France calculated these currents for Panama. (Report of the Academy, May 31, 1887.) The maximum calculated for the current was 1·17 metre per second, that is 2·27 knots an hour, and this with an exceptional tide of 6·76 metres of amplitude, which can only occur once a year. This current was calculated for a canal with restricted dimensions (about equal to those of the De Lesseps canal), 9 metres in depth (29 feet) at Colon and 11·50 metres ($37\frac{7}{10}$ feet) at Panama, and 21 metres ($69\frac{15}{100}$ feet) in width at the bottom.

If the climate of Panama were as perfectly dry as that of Suez, there would not be a shadow of justification for not admitting for Panama the solution that succeeded so admirably at Suez. The conditions of the fluvial waters is the reason to be invoked as an explanation of the rejection of the free opening with a narrow canal. The only complete solution of the management of fluvial waters of the rainy Isthmus of Panama leads us to admit a direct flowing into the canal of a volume of about 800 cubic metres per second, in case of exceptional swellings of the rivers. Even if we suppose that one-half shall flow into the Atlantic and the other into the Pacific, that would generate an additional current of nearly two knots in the sea-level canal projected by the Isthmian Canal Commission and still more of course in the narrower de Lesseps Canal.

In a canal as narrow and as shallow as the so-called sea-level canal, currents superior to two and a half knots would be inadmissible; we are, therefore, naturally led to increase the section in order to free the vessels from the objectionable action of the cumulated tidal and fluvial currents. Naturally the tidal currents will increase a little with the width and depth of the water-way, but the fluvial currents will decrease much more quickly, exactly in inverse proportion to the wet section of the navigable highway.

If we make again the calculations of the Academy of Sciences and apply them to the dimensions I have quoted above for the "Straits of Panama," we find that for the usual maximum tide of 6 metres of amplitude, the maximum current will be 2·93 knots. As

the wet section will be about six times greater than in the sea-level canal of the Isthmian Canal Commission, the flowing into it of 400 cubic metres a second will not produce more than a current of 0·3 knot. We may say then that the maximum current to which vessels will be exposed will not reach 3·3 knots, an absolutely insignificant velocity considering the width of 500 feet (152·50 metres) at the bottom, and the depth varying from 45 feet (13·72 metres) to 65 feet (19·82 metres).

The exceptional tide of the Academy of Sciences, which can only occur once a year, in September, would bring about a maximum velocity of 3·14 knots. If, by an extraordinary coincidence, it should meet with one of these exceptional floods, which requires the flowing during several hours of 400 cubic metres, we should not attain 3 knots and a half. This would probably not occur once in a century and would only last a few hours. We may, therefore, say that the real maximum current will be 3·3 knots.

We see, then, that the precedent of Suez guarantees the certain success of such an undertaking, as far as the currents are concerned. But even without this precedent we should have a right to rely on it implicitly, for I repeat that the "Straits of Panama" will have the dimensions of a very large navigable river, like the Thames or the Seine, flowing like them into a sea that has tides of 6 metres of amplitude. There cannot therefore be currents in the "Straits of Panama" more inconvenient to navigation than those of the Seine or the Thames.

As the maximum currents will occur in the neighbourhood of the Pacific (5 lunar hours after low tide), the question may be asked whether the soil of this region is consistent with the velocity of the water.

On this point there is no reason for alarm; the subsoil through which the bottom of the bed of the Straits will be dug is compact and resisting everywhere. It will be only necessary on the last eight kilometres on the Pacific side to protect the sides of the canal with stone embankments, the upper strata of the soil being soft there. This is an easy as well as inexpensive matter.

It results that no objection can be raised with regard to navigation, against the creation of the "Straits of Panama," that indispensable artery of the commerce of the world, the only route permitting a rapid and free passage in four or five hours, the only form of water-way free from all artificial work, locks or dams, the only one protected from accidents, explosions, destruction (in case of war), or earthquakes.

The Indispensable Tool for the Realisation of the "Straits of Panama"—the Dredge.—It is not sufficient to define the ideal type of communication between the oceans; it must also be practically realisable. Now, with the means generally employed, with those used by the Company presided over by M. de Lesseps during almost the entire duration of its existence, with those employed by the second Panama Company, the new Company, with those that the American Government is employing at the present day, such a conception is radically chimerical.

In the three cases quoted above the organ of excavation is the excavator or steam shovel, rolling on rails; the organ of transportation and dumping of the spoils is the car, rolling on rails. With this method, the method in the dry, the difficulties caused by the diluvian rain, in the preservation of the railroad tracks, are enormous. It is necessary for a relatively feeble production to have a considerable number of workmen in constant attendance. Accidents and running off the rails occur incessantly, because in a vast excavation work the tracks often have to be shifted to follow the terraces. Consequently they can neither be well fixed, nor well ballasted, nor well drained.

These necessities, combined with the brusque and violent tropical rain, the bad quality of the workmanship in that country where depression and fever are rife, and the clayish and slippery nature of the soil of the Isthmus, end in runnings off the rail, in accidents which occur over and over again, and which are the great, the only and the essential difficulty of the excavation of the Panama Canal.

The estimates prepared by the Isthmian Canal Commission, the American official authority entrusted with the execution of the Panama Canal gave, in September 1905, as the cost of the sea-level canal excavated in the dry, the following figure:—321,779,731 dollars, that is £64,355,946 sterling. This valuation comprised 7,000,000 dollars for the tidal locks, and 10,394,794 dollars for the masonry walls at Culebra, an erroneous conception now entirely abandoned.

We may, therefore, say that by overlooking these two elements of the work, the estimated cost of digging a lockless sea-level canal, 35 feet deep and 150 feet wide, was, in 1905, in round figures, 300,000,000 dollars, that is

£60,000,000. These figures were arrived at by the official American Commission after six years of study, and two years of effective work under its own management in the Isthmus.

The length of time for the execution of this canal was estimated at more than twenty years by the Commission in 1901, and in 1905 one may conclude from the documents of the Commission that it allowed twenty-two years. The volume of the excavations to be extracted for the sea-level canal thus conceived, having 35 feet depth below mean level from the origin on the Atlantic to Miraflores, K. 62, and 45 feet depth below mean level from Miraflores to the Pacific end, K. 75, with 150 feet bottom width, lateral slopes of 45° and bermes of 50 feet on each side of the canal at 10 feet above the water, is 205,000,000 cubic yards (156,000,000 cubic metres).

The volume of the navigable highway that I have called the "Straits of Panama," with an average depth of 50 feet below mean tide (45 at Colon, 55 at Panama), the width at the bottom being 500 feet, slopes at 45°, and bermes of 100 feet on each side, is about 600,000,000 cubic yards (457,000,000 cubic metres). The completion of the "Straits" would necessitate, roughly speaking, an outlay three times greater than that of the sea-level canal. According to the Isthmian Canal Commission's own figures, it would be necessary to spend 900,000,000 dollars, that is £180,000,000 sterling, or 4,500,000,000 francs, and to wait about 60 to 70 years to see the first vessel pass through it.

Such figures explain sufficiently why the rational and complete solution of the Panama problem. the opening of a water-way unobstructed by locks, having free openings on the two oceans, sufficiently wide to allow ships to navigate and to pass each other without being inconvenienced by the tidal and fluvial currents, has never been examined or discussed before September, 1905, when I submitted it to the International Consulting Board which met at Washington.

If I acted thus, it was not for the vain satisfaction of fixing a theoretical and chimerical term to the efforts of the engineers. In showing them the enviable and desirable end, I showed at the same time the practical way to reach it.

Since 1879, when the first International Congress was assembled by M. de Lesseps, until 1905, when the last one was assembled by Mr. Roosevelt, all the numerous Commissions by whom the Panama Canal was discussed, have all, without exception, forgotten one thing. This was the most important, the essential question—the mode of execution.

All these Commissions have admitted as implicit truth, as an axiom, that the Panama Canal would be excavated in the dry. They then discussed the maximum and minimum form compatible with this mode of execution from the narrow level canal closed by tidal locks on the Pacific side to the lock canal with a summit level, more or less high, in the centre of the Isthmus. (See Fig. K., p. 244.)

Now this particular mode of execution is not the only one as the various Commissions have thought. The excavation, transportation, and dumping may be effected in the dry, on rails, but it may also be effected on water. The excavation in the dry is not the only mode of excavating—it is also the worse, the more expensive and the poorer one. The defects which exist in temperate regions increase in incredible proportions under the climatological conditions of the Panama Isthmus.

With the excavation by floating dredges, transportation by barges and dumping in deep water, all the Isthmian difficulties vanish as if they had been touched by a magician's hand. (See Fig. M., p. 245.)

There is no more need of an enormous army of workmen, changing every minute some of the tracks, in order to follow the progress of the earthwork. There is no more need for the ceaseless care to be taken with the moveable tracks, which have necessarily poor foundations and cannot be disposed for supporting any heavy traffic. There is no more need for struggling against the sudden tropical floods which bring down on the tracks the mud torn up from the slopes of the cut, submerge them, ruin their foundations or bury them. There is no more need of stopping series of steam-shovels for the frequent runnings off the rails, which these unavoidable conditions of the soil and climate bring about constantly, blocking for whole days communication between the points of loading and points of unloading. There is no more need to struggle against the landslips which stop the excavation work, and when they take place on the lines of communication paralyze, by repercussion, both a considerable plant and a great number of hands. There is no more need to tax one's ingenuity to enable the trains to circulate over the dumping places where the rain causes frequent landslips. There is no more need for hesitation between this Scylla and that Charybdis, which is, either to have heavy trucks and powerful locomo-

Fig K.—Works in the Dry (Culebra in 1888). (See Appendix, p. 273)

FIG M—WORKS IN THE WET (DREDGE WORKING IN BLASTED ROCK—1888) (See Appendix, p 273.)

tives for excavating huge masses of earth which demands the heavy penalty of more frequent runnings off the rails, so difficult to keep in order, or to have lighter plant circulating more easily, but less powerful and carrying away insufficient masses. There will be no more need of exposing to the alternative sun and rain thousands of workmen who are struggling against nature, and consequently of enduring the sorrowful procession of fevers, and pneumonia which result from this inhuman work.

With the excavation on water by dredges, transportation on water by barges, and dumping into deep water by opening traps at the bottom of the barges, all these difficulties vanish. The carriage power of water is unlimited, and the most powerful organs for excavation may be employed without any drawback. As a matter of fact, dredges with buckets of 1 cubic yard (764 litres), are at present in current use. As there are 15 passing per minute they are capable of bringing up from the bottom more than 22,000 cubic yards in a day of 24 hours.

Making a very liberal allowance for stoppages and other causes of diminution of work, the most pessimistic of dredgers would not figure for one of these instruments on an effective yielding of less than 7,000 cubic yards (5,348 m.c.) measured in the excavation. And dredges of this capacity are not the most powerful ones. There are some in Great Britain which have buckets of about 2 cubic yards (1,528 litres), that is, which can give a useful and practical yield of 14,000 cubic yards (10,700 m.c.) per day, in the most unfavourable circumstances.

With the transport by water a barge can easily carry 2,000 tons of material, that is about 1,000 cubic yards of the heaviest ground (764 m.c.) measured in the excavation, and even more. The number of hands on board a dredge doing this enormous work would be fifteen men if it is a steam dredge, and ten men if it is worked by electricity. On board a barge there would be two or three. The dumping is automatic, and only requires the action of gravity.

All these men live on board the dredge and the barges, protected from the sun and the rain, their only work being to control and watch the machinery—that is, a work without any physical effort. The number of hands is very small; the men are absolutely protected against the inclemency of the weather, just as the plant is itself quite indifferent to rain or sun, night or day.

This admirable and complete solution of all the Isthmian difficulties is reflected naturally in the cost price. I will only mention the figures contained in the report of the International Consulting Board as the result of its inquiries of 1905.

In Appendix K. of the report we find that the excavation, in the dry, of earth and soft rock at Culebra cost for desagregation $11\frac{25}{100}$ cents, that is, $5\frac{5}{8}$d., or $56\frac{25}{100}$ centimes, and that the excavation, transportation, and dumping in the dry cost $60\frac{16}{100}$ cents, or 2s. $5\frac{8}{100}$d., or 3·038 francs, per cubic yard (0·764 m.c.).

In Appendix I. of the same report we find that the excavation by dredge, transportation, and dumping in the sea costs 7 cents, or $3\frac{1}{2}$d., or 35 centimes at Colon, and 8 cents, that is 4d., or 40 centimes, at Panama, per cubic yard (0·764 m.c.) The difference between these two latter prices of 7 and 8 cents. is accounted for by a longer transport in the second case.

It must be noted that the excavation in the dry was made with a new plant bought by the American administration, and that the excavation in the wet was made with the old plant from the first Panama company which had been out of use for 16 years. If the dredges and barges used had been of the power now usual, the prices would have been incontestably about one-half less and reduced, per cubic yard, to 3·75 cents, or $1\frac{7}{8}$d., or 0·185 francs. Mr. Welcker, the Dutch delegate on the International Consulting Board, remarked, in fact, as we see in the Appendix J, that the cost in Holland was 5 cents, or $2\frac{1}{2}$d., or 0·25 francs per cubic metre, including cost of transportation, to 6 or 7 kilometres (4 miles to $4\frac{1}{2}$ miles). This corresponds to 3·75 cents per cubic yard, the price we just named for actual dredging by large steam bucket dredges on a great scale.

Thus we see that the cost price of effective and real works, both in the dry and in the wet, reached by the International Consulting Board, establish a proportion of 1 to 16 between the cost of the excavation work, transport and dumping in the dry on rail and that effected on water in the Panama Isthmus. This enormous disproportion is entirely in harmony with what must be expected from two systems, one of which antagonises all natural forces while the other utilises them.

Gratuitous Electric Power.—But that is not all. The establishment of the dredges, water transport, and dumping is connected,

as I will show further on, with the establishment of a dam at Gamboa, across the Chagres, the large river that follows the canal for 27½ miles (44 kilometres) on the Atlantic side. The falls of this dam, erected across the river a little above the point where it enters into the line of the canal, will correspond to a minimum of about 32,000 horse-power, permitting of the free distribution of power to the dredges, barges and instruments for breaking the rock which, by the way, is generally very soft. This electrification of the whole of the great working ground would again allow of an important reduction in the already small cost of dredging and of the transportation of the spoil by water.

Rock-dredging.—The following question might be asked:—However great may be the economy in the excavation of the loose ground by the dredge, is not the removal of the submerged rocks an insurmountable obstacle? We now touch on one of the technical questions ignored singularly enough even by engineers reputed as skilled and competent.

Twenty-five years ago, when I was at the Ecole des Ponts et Chaussées (school for engineers of the government of France), we were taught that this was an operation costing 30 to 35 francs per cubic metre, £1 sterling per cubic yard (1 cubic yard equal 0·764 cubic metre). More recently still we saw the Isthmian Canal Commission including dogmatically (Report of November 16th, 1901) in its list of standard prices, that the extraction of rock under water would cost 4 dollars 75 cents a cubic yard (19 shillings or 23·75 francs). Such exorbitant prices still dwell in the brains of many engineers. In 1885 at Colon, being obliged to remove some submerged rock, I mined it by a process which reduced it to pieces as large as pavement stones and I dredged it afterwards. The dredge did not seem to make any difference between such perfectly broken rock or ordinary sand. This cost me, in spite of the rudimentary method of mining employed, about eight francs per cubic metre, or six francs a cubic yard, that is one-fourth of the price which the Isthmian Commission, composed of the most eminent American engineers, approved sixteen years later; and yet, since my work of 1885, there has been great progress made. Lobnitz, the eminent dredge builder of Renfrew, invented 18 years ago the *derocheuse* (rock destroyer) for the Suez Canal. It consists in a heavy steel chisel ending in a moveable point, which reduces the hardest rocks into pieces the size of a man's head. The heavier the chisel the greater the amount of work accomplished and the less the cost per cubic yard. The weight of the chisel has gradually increased from four to twenty tons. It will certainly reach fifty tons, and then the price of the breaking of rock will be insignificant. Even at the present day the crushing of rocks of average hardness is less than one shilling per cubic yard.

In *Engineering*, August 17th, 1906, there is a note given by Mr. Hunter, chief engineer of the Manchester Ship Canal, stating that the price of crushing rock in the ship canal during ten months work, was less than 9d. per cubic yard, and that in spite of the loss of time due to the passing of vessels. The minimum quantity of work per month was 5,622 cubic yards (4,294 m.c.), the maximum quantity, 10,180 cubic yards (7,778 m.c.), the average quantity, 6,403 cubic yards (4,892 m.c.). The minimum was therefore 225 cubic yards per day. (See Fig. I., p. 248.)

M. Quellennec, Consulting Engineer of the Suez Canal and Member of the Consulting Board, handed over to that body a memorandum stating that the price of crushing rock at Suez was 25 cents per cubic yard by the same Lobnitz method. By one of the most singular and inexplicable omissions, this very important document has never been inserted in the Consulting Board's report, nor in any of the annexes. Neither has any mention been made of the data that Mr. Hunter must have furnished also as a member of the Consulting Board, on the results obtained in the Manchester Canal, later published in *Engineering*, and which are in absolute conformity with those obtained at Suez. These economical results were obtained with chisels of 12 tons at Manchester and 15 tons at Suez.

Comparing the Culebra rock with that of the Manchester Canal, we find that, except in the case of a few dikes, it is infinitely softer than the sandstone of the Manchester Canal. The Manchester price is, therefore, a maximum, and there is no doubt in my mind but that the price of crushing would fall below 11 cents, the present price of mining with explosives in the dry—even if the Lobnitz chisels were worked by steam. The free use of electricity from the Chagres Falls at Gamboa, and the increase of weight in the chisels from 15 to 40 or 50 tons would certainly reduce the crushing to a few pence, surely to less than half the cost registered at Manchester.

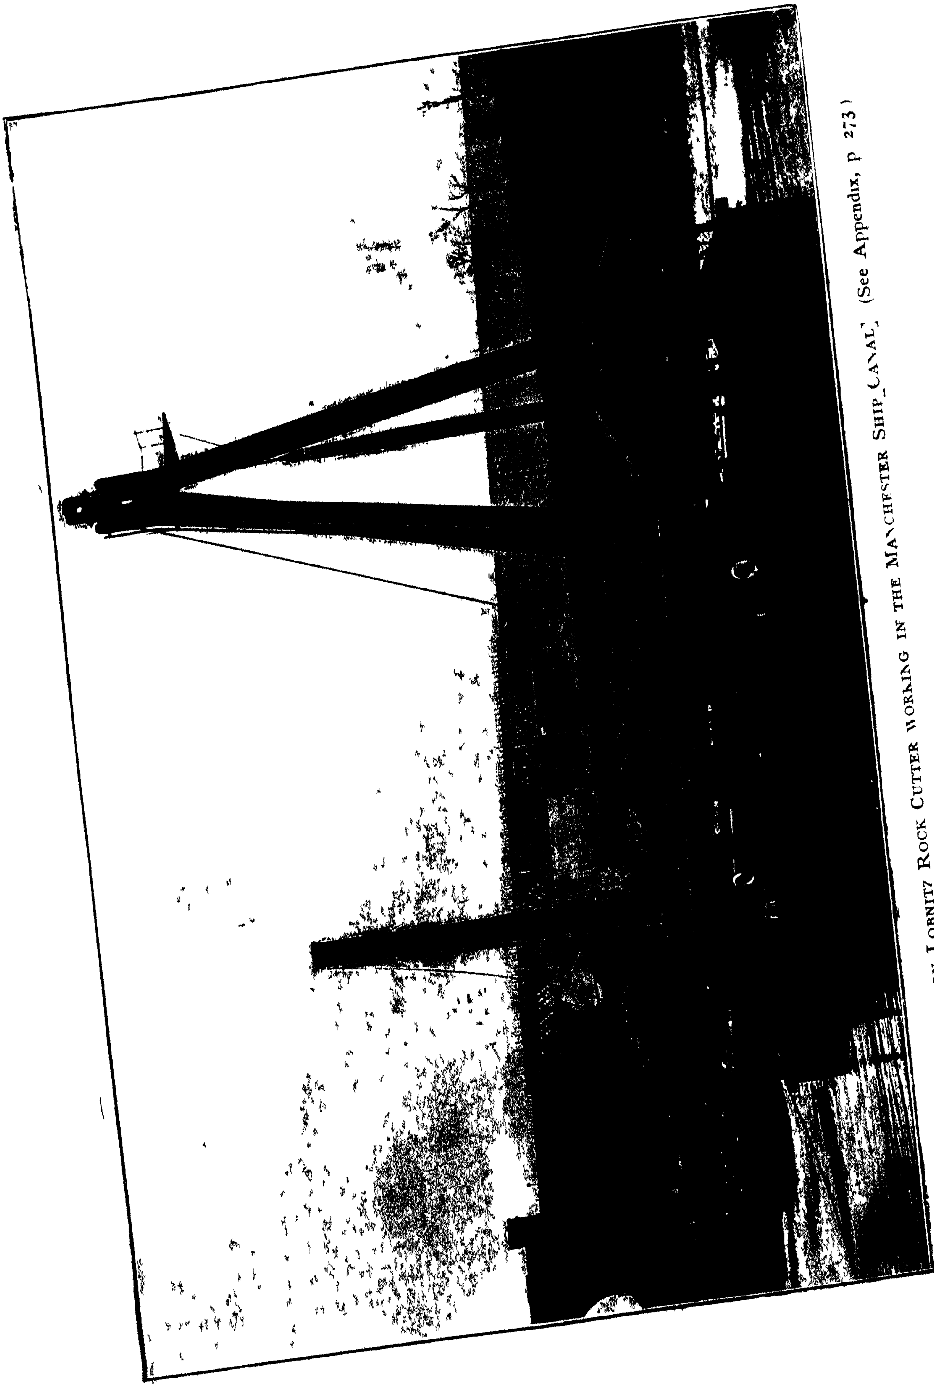


Fig. 1.—Twelve ton Lobnitz Rock Cutter working in the Manchester Ship Canal. (See Appendix, p. 273.)

Why did the Consulting Board not insert the memorandum of M. Quellennec, the Consulting Engineer of the Suez Canal, on the real cost price of the crushing of rock at Suez? Why was no mention made in that report of the information that Mr. Hunter, Chief Engineer of the Manchester Canal, must have supplied? There is, in Appendix I. (p. 273), proof that this important information had been given to the Board.

Mr. Wallace, the first engineer in chief of the Panama Canal, appointed by the American Government, said (see p. 380 of the Report) :—

"As regards the excavation of submerged rock there is a process which has not been mentioned in any of these reports, but I think that M. Bunau-Varilla has spoken of it; it is the breaking of the rock by what is termed chisel-work.

Mr. Hunter:—You mean the Lobnitz system?

Mr. Wallace:—I do not know what you call it.

Mr. Hunter:—It is perhaps not necessary to dwell on that subject. We have discussed it at length here. It is a proceeding with which M. Quellennec and myself happen to be both extremely familiar."

The silence of the Board in this report on the facts that the two eminent engineers of the Manchester and Suez Canals must have supplied, is all the more suspicious as the price adopted by it for the excavation of submerged rock is 2½ dols., that is ten shillings, or 12·50 francs, per cubic yard; whereas according to the figures for the crushing given by the English delegate, Mr. Hunter, in the *Engineering*, the maximum price of rock breaking ought to have been 18 cents American money), and the price of subsequent dredging ought to have been the one supplied by the Dutch delegate, Mr. Welcker, 3¾ cents (American money). The price of the removal of rock under water ought then to have been fixed by the Board not at 10s. a cubic yard, but at 10⅞d., that is to say, at a price more than ten times smaller. And even such a low price ought to have been considered as a maximum on account of the economy that will arise from the use of the free electric energy from the Gamboa lake, for supplying motor power to the dredges, to the Lobnitz rock crushers, and to the barges used for transport. It could, therefore, be expected to be brought down to 7½ pence per cubic yard in the average Culebra rock. The Consulting Board preferred to this logical and experimental price the arbitrary one of 10 shillings.

We may now sum up this exposition of the advantages of the method of dredging substituted for the method in the dry, by saying that it is 16 times more economical when the ground does not necessitate preliminary desagregation. If the ground necessitates such preparation, the crushing by the Lobnitz process, in the wet method, costs less than mining in the open air by the dry method. Such is the scientific truth which results from the experience of great hydraulic undertakings pursued at Suez, Manchester, and a number of other places. I do not hesitate to say that this figure of 11 cents, or fivepence halfpenny, or 0·55 francs, which I consider a maximum for the desagregation of the Culebra rock by heavy chisels of 40 to 50 tons, worked by electricity, and which may appear bold, will appear less so when we consider that the Japanese at Okasaki and at Yokohama, in a soft rock just like that of Culebra, with small Lobnitz chisels worked by steam, spent about four times less per cubic yard.

In the account I gave in September, 1905, before the Consulting Board, of the "Straits of Panama," I did not want to go to the extreme with regard to the advantages of the system of excavation by water, and I limited myself to asking that it should be admitted that it was three times more powerful, and three times more economical on an average, than work in the dry, whilst it really is 16 times more so in a loose soil, and 4 times more so in a rocky soil. I thought that this extreme moderation would permit of an easier approval of my proposal. This humble proposition sufficed, in any case, to prove that it would not cost more money or more time to make the "Straits of Panama" by dredging, than to make the narrow sea-level canal closed by tidal locks with excavators in the dry. But this moderation on my part did not disarm the incoercible partisans of the working in the dry. The system was rejected by the Consulting Board. They could not be convinced either by the grandeur of the end that could be reached or by the evidence of figures collected by the Board itself as to the cheapness, practicability and power of the new method.

Erroneous Arguments Invoked for Rejecting the Dredging Method without which the "Straits of Panama" are Chimerical.—The Consulting Board was content to pass over in silence the eloquent figures relating to the extraction of the rock under water in the Manchester and Suez Canals, and adopted a unit price ten times higher than that resulting

from these experiences. This allowed the Board to condemn the method proposed.

This is what we find on page 32 of the report of the majority of the Consulting Board, signed by Messrs. Geo. W. Davis, W. Barclay Parsons, and Wm. H. Burr, Delegates of the American Government; Mr. Henry Hunter, Delegate of the English Government; Eugen Tincauzer, Delegate of the German Government; and J. W. Welcker, Delegate of the Dutch Government and Kellennec, Chief Engineer of the Suez Canal:—

"The claim made by M. Bunau-Varilla that the excavation can be done at low cost rests mainly on the expectation that by the use of electric power, developed at the Gamboa dam and distributed along the line, the expense for fuel for generating steam will be eliminated, and the cost of all mechanical operations reduced by what appears to the Board to be a much exaggerated estimate of the economies thus affected, and on the further expectation that excavation can be made at very much less cost by dredging than in the dry. This reduced cost of dredging is probably true for sand, clay, and other materials that can be moved without being shattered by some preliminary process, but nearly all the materials to be dredged for the transformation are classified in the Board's estimates as rock, and will have to be loosened by blasting under water, by breaking or pulverising—as in the Lobnitz method—or by such other methods as may be devised. Moreover, it must be remembered that the greater part of the dredging is to be done under 40 to 50 feet of water, which will add much to the cost. The unit prices adopted by the Board represent its best judgment in regard to the cost of excavating the several classes of materials which the transformation would require, with the best methods and appliances now in use."

It is hardly necessary to point out the fundamental errors which this paragraph contains:—1. In a dredge where the motive power is free, it is of no importance whatever whether dredging takes place at 20 or 50 feet. 2. It is absolutely false to state that almost all the material to be excavated is rock. The Isthmian Commission admitted that there was about one quarter soft rock, one quarter hard rock, one half earth in the canal (outside of the maritime sections)—that is, from kilometre 24 to kilometre 62. The person who drew up this part of the report evidently considered it necessary to make this assertion, which is so contrary to all material facts, in order to increase the importance of the illusory objections drawn from the false price of excavating rock under water. This erroneous assertion harmonises with the adoption of the ten times too high and prohibitive price of 2·50 dollars for rock excavation, and with the suppression of the information of Messrs. Quellennec and Hunter regarding the veritable prices established at Suez and Manchester. Thus, the necessary system of the substitution of the dredge for the steam-shovel was condemned in 1905 for this imaginary reason: "The ground is too hard."

The first Commission formed after the failure of the old company had also come to the same conclusions, and in 1890 had condemned the dredging system that I had installed in the centre of the Isthmus on both sides of the higher part of the Culebra cut. I had, in fact, inaugurated the dredging of the Culebra cut at the end of 1888, but the dredging work was interrupted in its commencement by the financial crisis, which paralysed the completion of the canal. The Commission, consisting of well-known technical authorities, in 1890, also condemned this method, but this time it was for a contrary reason to that which in 1905 was brought forward by the Consulting Board.

"The idea of turning the principal enemy—water—into an auxiliary is certainly ingenious," said the Commission of 1890, "but it is impossible, the ground is too soft. Perhaps the idea may be taken up later when the harder ground below is reached." Reasons are never wanting to a judge who is anxious to condemn.

Is it also necessary, in order to show the nature of the objections raised by the Consulting Board, to call attention to the fact that, in their report they have inverted the two factors of the economy that the system which I proposed will realise.

The report represents the employment of the free electric power from the falls of the Gamboa lake as the principal element from which I expect to derive economy, while in reality it is only the secondary element. It presents further as a subordinate element what I presented as the keystone of the system of construction, its principal and essential element: the substitution of work on the water for work in the dry. The "Straits of Panama" cannot be made except by dredging, but whether the electricity is free or not means simply the difference between the cost of 24,000 horse-power during ten years generated at a steam central station, and the cost of harnessing waterfalls giving 48,000 horse-power.

Admirable Conditions Presented by Nature for the Employment of the System of Excavation on Water.—After having shown the natural privilege of the dredging method, to the brilliant qualities of which

its enemies have not been able to oppose anything but an illogical and baseless condemnation, I will now show with what marvellous perfection it can be adapted to the present conditions of the Isthmus.

If we cast a glance over the profile in length of the natural ground we find three quite distinct zones:—(See Fig. B. or D. or E. in the Supplement and Explanatory note in Appendix, pp. 270-272.)

1. The central mass extending from K. 46 to K. 57 (mile 28·38 to mile 35·42).

2. The high valleys of the Chagres and of the Rio Grande, K. 24 to K. 46 (mile 14·90 to mile 28·58) on the Atlantic side, and K. 57 to K. 62 (mile 35·42 to mile 38 53) on the Pacific side.

Lastly, the low valleys, the maritime sections of the two rivers, the parts where the bottom of their bed is below the average level of the sea. They extend, on the Atlantic side, from K. 0 to K. 24 (mile 0 to mile 14·90), and on the Pacific side from K. 62 to K. 75 (mile 38·53 to mile 46·62).

The elevatlon of the ground on the axis is on an average on the total length (75 kilometres or 46·62 miles) 14 metres 55 ($47\frac{7}{10}$ feet) above the average level of the oceans, but this altitude of the ground varies considerably in the three natural groups that I have mentioned.

In the central mass the average elevation is 181·7 feet (55·43 metres); the maximum elevation of the ground on the axis is 333 feet (101·66 metres), it is 149·4 feet (47·57 metres) at the beginning of the section K. 46, and 110·7 feet (33·78 metres) at the end of this section K. 57.

Between the maritime part, Atlantic side, and the central mass, that is to say between K. 24 and K. 46, the average altitude is not more than 47·9 feet (14·65 metres). In the corresponding section, that is from K. 57 to K. 62, on the Pacific side, the average altitude is 53·3 feet (16·25 metres). Lastly, in the maritime parts the average altitude falls to 11·9 feet (3·68 metres), on the Atlantic side from K. 0 to K. 24, while on the Pacific side it falls below the average level of the sea and is only −2·3 feet (−0·69 metre).

This glance at the configuration of the Isthmus shows that the heaviest part of the excavation work will have to be done over the 11 kilometres extending between K. 46 and K. 57. In fact, out of the volume of about 205,000,000 cubic yards which would have to be excavated over the 75 kilometres of the canal in order to obtain the sea-level canal of the Isthmian Commission (Project of 1905: 35 feet in depth, 150 feet in width at the bottom, and 50 feet berme), there is not less than 114,000,000 cubic yards or 87,000,000 cubic metres to be extracted from the central mass on the 11 kilometres length. Thus we have more than half the total work concentrated there.

Almost the same may be said in regard to the "Straits of Panama," with its 500 feet of width, its average depth of 50 feet, and its bermes of 100 feet. The straits necessitate an excavation of 600,000 cubic yards (458,000,000 cubic metres). Of this amount 260,000,000 cubic yards (199,000,000 cubic metres) must be excavated from the 11 kilometres of the central mass. In this case it is not quite the half of the total excavation, but about four-ninths.

The Gamboa Lake and its part in the Excavation of the Straits.—If we glance at the map of the Isthmus we shall see that the Chagres, the principal river of the Isthmus, enters the line of the canal at K. 45 (27·96 miles). (See Fig. C, p. 252.) Just above this point the river passes between two mountains, the Cerro Obispo and the Cerro Santo Cruz, both formed by a hard and homogenous pudding stone. The rocky slopes of the two mountains meet under the bed of the Chagres, about eleven metres lower than this bed, or in other words, at the sea level. The whole, when cleared of sediment and soft rock, forms a sort of V about 500 feet (150 metres) wide at the bottom, and with an opening of about 2,250 feet or 675 metres at an altitude of 160 feet (48 metres) above the sea level. This is an admirable site for a masonry dam. Only the foundations would have to cross a layer of 11 to 14 metres of alluvium, over which the river flows. This part can be made either by pumping the water from the excavations or by using compressed air.

The old Panama Company had planned a dam at this place in order to control the floods of the Chagres by the formation of a regulating lake, the maximum elevation of which was to be also 60 metres above sea level. By an almost incredible error, the new Panama Company had, without any plausible reason, abandoned this perfect site and transported to Alhajuela, 16 kilometres (10 miles) higher in the valley, the dam which it was intended to construct there.

The Isthmian Canal Commission, in its

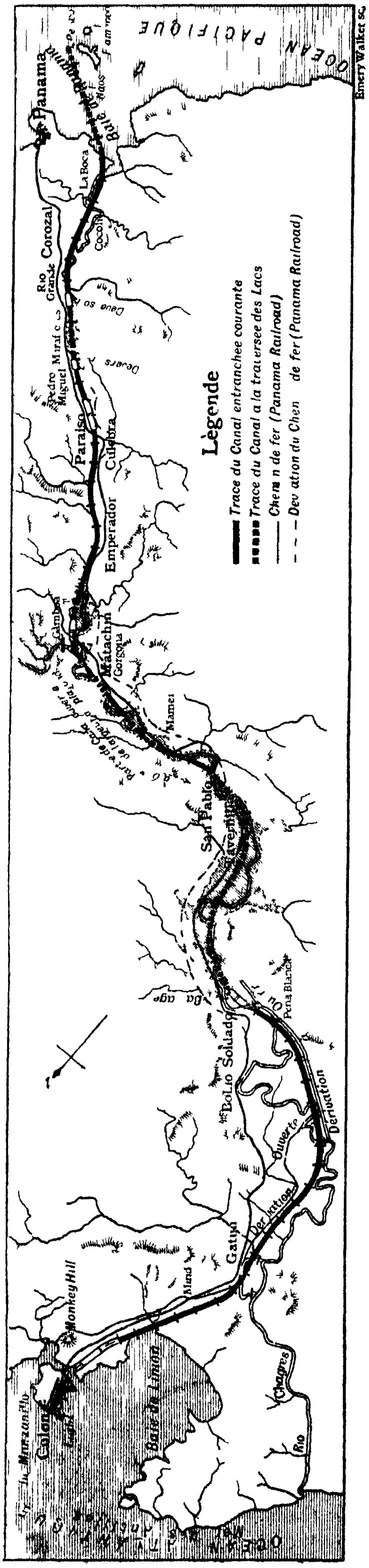

FIG C —PLAN OF THE PANAMA HIGH LEVEL LOCK summit elevation 130' (See Appendix p 271)

project for 1905 for a sea level canal, came back to the ideas of the old company, and again proposed the same site and same maximum level (200 feet above sea level) The erection of this dam and the subsequent formation of the lake, is an absolute necessity for the execution of the Straits of Panama, the essential organ of the excavation by dredging

In addition to the fact that the old company, and later the Isthmian Canal Commission, had destined the Lake of Gamboa to be the regulator of the Chagres floods, I proposed —

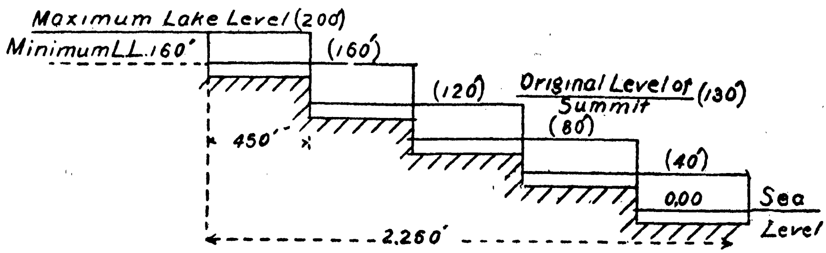
1 That it becomes the receiving basin for all the material dredged, from K 24 to K 62, that is to say, on the whole extent of the Isthmus with the exception of the maritime parts of the two valleys

2 That it becomes the generator of the electric power that will feed all the plant of the excavation and transportation

3 That it furnishes, by simple diversion into the dredging basin, both the water necessary for the maintenance of the level necessary for navigation, and the water enabling the transport barges to pass through locks from the level of the works to the level of the lake

A few figures will suffice to prove that the Lake of Gamboa can easily fulfil the four functions which are allotted to it The surface at 200 feet (60 metres) elevation above sea level is 11 209 hectares, or 43 3 square miles At elevation 170 feet (51 85 metres) it is 7,975 hectares (30 8 square miles) At 132 feet elevation (40 26 metres) it is still 3 857 hectares (14 9 square miles) The volume of this lake between the natural ground and the surface at elevation 200 feet (60 metres) above the sea, is more than 2,000 million cubic metres (2,600 million cubic yards) At elevation 160 feet, its capacity is still 950 million cubic metres, or more than twice the volume of the entire "Panama Straits"

I have proposed to devote all the space comprised between the surface at elevation 160 and the surface at elevation 200 to the part of controller of floods and water store It therefore becomes evident that there remains below the minimum level much more than is necessary for the storage of all the dredged ground It must be remarked that this magnificent depository basin is situated at about half-a-mile from the origin of the cut of the central mass, and that nothing is easier than to establish flights of locks between the working summit and the lake on the rocky sides of the hills which separate the lake and the canal cut.



We see that the system of dredging is certain of its most indispensable element of success; the presence in the centre of the Isthmus of a large and deep dumping basin, capable of receiving far more spoil than necessary.

The Central Mass now Presents Perfect Conditions for the Dredging.—Now we come to the dredging works proper. The central mass, with its maximum altitude of 333 feet, is now pierced, thanks to the work executed by the French companies, at the elevation of 157 feet above the sea (48 metres) except for a couple of hundred yards which have been kept 35 feet higher for the passage of trains. We can now pass from one ocean to the other without rising more than 157 feet (48 metres). Then by closing at the two extremities of the 11 kilometres of the central mass, by two small dams, the valleys of the Obispo and of the Rio Grande, to a level equal or superior to 157 feet (48 metres), all the central mass will be covered with a sheet of water, and dredges can be installed. But these dredges must float as high as possible in order to reach the highest ground.

In adopting as the first dredging level 170 feet (51·85 m.), the ground situated below this altitude of 170 feet would be removed by dredging. As to the higher grounds, it would be necessary to work them in the dry, and to throw them into the dredging summit from whence they would again be taken up by the dredges, and evacuated into the Lake of Gamboa. Another plan might consist in unloading them into the barges that will carry them into the lake. The volume thus to be treated amounts to about 25 million cubic metres (33 million cubic yards). (See Fig. E. in the Supplement and Explanatory note in Appendix, p. 272.)

As we have frequently said, the essential difficulty in the dry does not consist in the excavation; it consists in the transportation and the dumping.

The excavation of the higher part of the cut, with the immediate precipitation of the waggon-loads from the height of fixed stockades into the dredging summit, will become relatively easy. The actual cost of the excavation would thus be easily reduced by one half, according to the decomposition of the expenditure furnished to the Consulting Board, and the excavation power could be easily quadrupled. These excavations reach at present 250,000 cubic yards per month in the Culebra Cut. We might, therefore, reckon that the clearing of the upper part could be carried out in this manner at the rate of 12,000,000 cubic yards per year, that is, in three years.

As the average production of the dredges in the main cut may be, as I will show, based on an annual production of 30,000,000 cubic yards, there will result from this digging out a surplus time of two years, and a surplus expenditure of about £2,400,000 sterling, or 12,000,000 dols., or 60,000,000 francs. After this first work had been executed, the dredges would work regularly, lowering successively the level to that of the oceans.

On the 11 kilometres of the main cut, 16 large dredges could easily be installed which, even with the absolute minimum returns of 7,000 cubic yards per 24 hours, would produce more than 100,000 cubic yards per day, or 30,000,000 cubic yards per year.

The 260,000,000 cubic yards (199,000,000 cubic metres) of the main cut would therefore be removed in little more than eight and a-half years, if we had not to reckon two years more for the removal of the upper part. The duration of this cyclopean work would, therefore, not exceed ten and a-half years, from the time when the dams and locks giving access to the lake would be opened. As we must reckon four to five years for this preliminary work, the execution of the Panama Straits is possible in fifteen years. This period, which is so short if we compare it with that of 60 to 70 years required by the working in the

dry, is not to be considered optimistic. With the dredges — and especially the electric dredges—the delays would be reduced to a strict minimum and the yielding which we have admitted for the dredges, allows a margin of security equal to the figure itself. Neither can we admit that the work to be executed, in addition to that of the main cut, might delay the term fixed for the end of the undertaking. In fact, in the maritime parts of the Isthmus, between Colon and K. 24, on the Atlantic, and between K. 62 and Panama, on the Pacific side, the ground would be excavated and then transported to the sea or pumped and deposited by water on the banks of the valley. (Excavation on the maritime section of the Atlantic side, 87,000,000 cubic yards; excavation on the maritime section of the Pacific side, 37,000,000 cubic yards.) As regards the sections comprised between the maritime parts and the main cut, they would be dredged like the preceding ones, and the material would go into the Lake of Gamboa.

When the level of the water will have descended from 170 feet to an altitude of 60 feet in the main cut, dams across the Rio Grande and the Chagres will spread to this same level the sheet of water from K. 24 to K. 62. New dredges would be operated, independently of the others in these sections, and the spoil from them would be thrown into the Lake of Gamboa, either by transportation through the locks or by pumping them into the lake. Of course a part of the spoil could be also in these sections deposited or pumped on the sides of the valleys, and the work of dredging begun before the dredging level in the Culebra cut is lowered to 60 feet elevation. (Excavation from K. 24 to K. 46—170,000,000 cubic yards in the Chagres Valley. Excavation from K. 57 to K 62—45,000,000 cubic yards in the Rio Grande Valley.) At this period, the point of access for the barges to the Lake of Gamboa, the foot of the flight of locks being near K. 46, will be about the middle of the long dredging summit extending from K. 24 to K. 62. It would be at about three kilometres (two miles) from the mathematical centre of this summit. In this manner the average of the distance to be gone over in the dredging summit, which was 5½ kilometres in the first phase, will be 11 kilometres in the second. It will be, therefore, very small during the whole period of excavation.

Nature of the Ground in the Culebra Cut.—The mass of the Culebra cut is composed, through almost its entire length, of hard clay, which barely deserves the name of rock. The Isthmian Canal Commission, in their report of 1901, have given a very accurate definition of the nature of the rock:—

"There is a little very hard rock at the eastern end of this section (Culebra), and the western two miles are in ordinary material. The remainder consists of a hard, indurated clay with some softer material at the top and some strata and dikes of hard rock. In fixing the price it has been rated as soft rock, but it must be given slopes equivalent to those in earth. . . . . Probably nine-tenths of the material would naturally be classed as hard clay of stable character."

If we admit that the average hardness is that of the sandstone of the Manchester Canal, we shall make an estimate probably two or three times too high, surely double.

Quantity of Hydraulic Power Necessary.—As we have seen already, the figures furnished by Mr. Hunter, Chief Engineer of the Manchester Ship Canal, and published in *Engineering* of August 17th, 1906, establish the fact that the minimum amount of rock broken, with a 12 tons cutter, was 225 cubic yards per day, with two shifts working ten hours each, which corresponds to about 270 cubic yards for a 24 hours' work with three shifts of men. Let us admit the extreme minimum of 200 cubic yards per day. Therefore, if the $\frac{9}{10}$ths of the whole of the Culebra cut, instead of being hard clay scarcely fit to be called soft rock, were of the hardness of the average Manchester rock, it would require 500 rock cutters of 12 tons to disintegrate and make dredgable 100,000 cubic yards per day. But, as we have said, owing to the softness of the Culebra rock, the Lobnitz rock cutters will on an average yield three times as much. If, for safety, we reckon only twice, we should be led to say that 83 pontoons with three rock cutters of 12 tons on board would do the work. As the cutters are raised about 10 feet (3·05 metres) every 15 seconds, it would require a mechanical power of 32 horse-power per cutter, that is 8,006 horse-power for the whole, which, reckoning only 50 per cent. for the yielding, will correspond to 16,000 horse-power at the falls generating the power. The results would be considerably improved by increasing the weight of the cutters from 12 to 40 or 50 tons, but we will not take this into account so as not to base our calculations on experiments yet to be made.

The dredging would be made by 16 electric bucket dredges, every dredge having five barges carrying 2,000 tons for the transportation and disposal of the spoil. These

barges would be supplied with propelling electric apparatus of 50 horse-power. Reckoning an average employment of 200 horse-power for each dredge, and 200 horse-power for the five barges, the extraction and the transport would also require 8,000 horse-power.

The whole of the operations of the works on the central mass, K. 46 to K. 57, will, therefore, necessitate a fall of water of 32,000 horse-power. The works to be made on the sides of the central mass from K. 24 to K. 46 and from K. 57 to K. 62, will require the assistance of naval plant of equal power but without Lobnitz rock cutters, and this will demand a new hydraulic power of 16,000 horse-power, that is 48,000 horse-power in all. The whole of these requirements will be assured by the falls of the Gamboa and Bohio Lakes.

The average supply from the Chagres at Gamboa, according to the regular returns made during a period extending over more than the last 20 years, is 100 cubic metres per second, but during the three months of dry season it falls much lower than the average.

The volume of the Gamboa Lake comprised between the elevation 170 feet (51·85 metres) and elevation 200 feet (61 metres) is 877,668,000 cubic metres. If the lake is full at the end of the rainy season, it can supply during more than 100 days 100 cubic metres a second, without falling below the level of 170 feet, and without receiving any water from the upper valley. This reserve thus ensures the constancy of the average supply during the dryest period.

As 30 cubic metres per second will be required for the working of the locks giving access to the lake when the dredging is in progress, between K. 24 and K. 62, 70 cubic metres would remain free for the generation of power. The Gamboa fall should be reckoned between the maximum level of the Bohio Lake (60 feet) and the minimum level of the Gamboa Lake (170 feet), that is, 110 feet (33·55 metres). The hydraulic power, therefore, is 31,200 horse-power. It is therefore practically equal, under the worst conditions, to the demands of the excavation of the central mass.

On the other hand, at Bohio, we will have at our disposal a minimum of 100 cubic metres running from Gamboa, and, on an average, of 150 cubic metres a second.

The supply of 100 cubic metres, falling from the minimum height of the Bohio Lake (50 feet or 15·25 metres), will produce 20,000 horse-power. The minimum total power developed will be, therefore, more than 50,000 horse-power during the period of the lowest waters, and will satisfy the requirement of 48,000 horse-power necessary for the work outside of the maritime parts. This latter work will be carried out by steam power; the spoils will be transported into the sea or pumped on to the valley sides.

Amount of Men and Money necessary.——After noting that Nature has placed exactly at the desired spot the necessary mechanical powers for this gigantic displacement of masses, let us see how few men are necessary to direct this power in order to attain the end in view. The working of the central mass will require 16 electric dredges worked by 10 men, 85 pontoons worked by 9 men, 5 barges for each electric automotor dredge, each worked by 2 men. This makes an effective force of 1,067 men, and with three gangs at work, 3,201 men per day, or 3,500 men if we include the staff of electricians, men at the locks and the workmen who are attending to repairs, &c. This force will be increased by 1,000 men when the valleys of the Chagres and the Rio Grande are attacked, for in these regions the almost complete totality of the ground is loose and directly dredgable. The immense work to be carried out between K. 24 and K. 62 only demands, therefore, a force of from 3,500 to 4,500 men, that is an average of 4,000 men.

As is necessary in tropical countries, instead of repairs made at the shops new pieces will take the place of those out of order, and repairs on the spot will be reduced to a minimum. Admitting the excessively high average salary of 12 shillings, that is 15 francs, or 3 dollars, per day of eight hours, so as to include in this amount the expenses of the superior technical management, the daily expense would be 2,400 pounds sterling, or 12,000 dollars, or 60,000 francs; that is, for 300 days of work a year, an annual expenditure of 720,000 pounds sterling, or 3,600,000 dollars, or 18,000,000 francs.

The expense in ten years and a-half would be 7,560,000 pounds sterling, or 37,800,000 dollars, or 189,000,000 francs for the work exclusive of the maritime parts	£7,560,000
If we add—	
1. An equal amount for repair pieces	£7,560,000
2. A sum of £5,000,000 for construction of the locks giving access to the Lake of Gamboa, the Gamboa dam (this latter work was valued at £1,000,000 by the	

Isthmian Canal Commission), the smaller accessory dams, the electric installations, &c.	£5,000,000
3. A sum of £2,000,000 for the excavations to be made in the maritime parts of the Isthmus, K. 0 to K. 24 and K. 62 to K. 75	£2,000,000
4. A sum of £4,000,000 for the dredging, transporting, and rock-crushing plant	£4,000,000
5. A sum of £2,400,000 for surplus expenditure pertaining to the excavation of the part of the Culebra cut above 170 feet of altitude	£2,400,000
We reach a total of	£28,520,000
and by adding for unforeseen contingencies	£1,480,000
we obtain the total above-mentioned of	£30,000,000

or 150,000,000 dollars, or 750,000,000 francs.

The mere statement of the elementary figures shows what a considerable margin exists between the valuation and the probable reality. I have the firm conviction that the total expense will not reach two-thirds of this amount, and will be limited to twenty million pounds sterling, or 100,000,000 dols., or 500,000,000 francs, that is one-ninth of what the execution of this gigantic conception would cost in the dry. Those who have a less optimistic view about the cost of dredging operations may double or even treble the cost of labour and repair pieces. They will not reach more than £60,000,000, a still perfectly admissible sum for such a result. It is this over-conservative estimate of £60,000,000 which I gave to the Consulting Board in 1905.

After having shown how the rational utilisation of the topography and the dynamics of the Isthmus allow of the easy and low priced execution of the hitherto chimerical work of the creation of a Straits across the Isthmus of Panama, let us examine what this magnificent road would be when once brought into existence.

Management of the River Floods.—The three large rivers of the Isthmus are the Chagres and its two large tributaries, the Rio Trinidad on the left and the Rio Gatun on the right. They fall in the Chagres between Bohio and the sea. The Chagres, domesticated by the lake formed by the Gamboa dam, would have no more alarming floods and would empty into the Straits the pure lake water. The highest floods measured at Gamboa during a quarter of a century have risen to 1,600 cubic metres a second; the lowest water noted corresponds to a supply of 11 cubic metres per second.

There was a flood in 1879, which is said to have risen to 2,040 cubic metres per second at Gamboa, but it was not measured and is a mere conjecture. The duration of the rise of the floods is short and lasts at the most 48 to 72 hours. Caused by the passage of a cyclone they disappear with it. The total of the mass of water delivered by the Chagres at the rate of 1,600 cubic metres per second, in 48 hours continuously, is 276,000,000 cubic metres. It must be considered as a practical maximum of exceptional flood. If nothing flows off into the Straits, it corresponds to a variation of the lake level of 2·9 metres, or 9 feet 8 inches.

We have said that the volume of the lake at elevation 200 feet, is about four times the volume of the excavation of the Straits of Panama, which will be dumped into it. It will lose, therefore, by this operation, less than a quarter of its surface, since the spoils will be deposited against the dam in the deepest part of the lake.

These figures show with what facility the control of the Chagres waters will be effected by the Gamboa Lake after the excavation of the Straits. Between K. 24 and K. 44 the Straits will receive direct the waters of the small rivers which will flow into it. Their sediments are slight, like those of the Chagres, and it will be easy to diminish them still more by breaking their slopes by means of small dams. The volume of water supplied by these small rivers rises in these exceptionally short and rare floods to 600 cubic metres per second. Even if we figure on 800 cubic metres per second every three or four years, for 48 hours, the section of the Straits being on an average about 2,500 square metres, this supply will only produce a current of 0·32 metre per second, that is 0·6 knot, if all flows on one side; 0·3 if half goes to the Pacific, and the other half to the Atlantic. Between K. 24 and the sea, the old bed of the Chagres, completed by river diversions which are existing with the exception of one that remains to be opened, will take straight to the sea the waters of the Trinidad, of the Rio Gatun and of the other small tributaries falling between the Atlantic and the kilometre—24. Therefore no contact will exist between those rivers and the Straits in the maritime part of the canal on the Atlantic side.

On the Pacific slope the rivers have insignificant floods and will flow into the Straits

direct. Thus the question of the Isthmus rivers is completely solved with the Straits, while with a sea-level canal of narrow section the problem is difficult to meet completely. It has caused a great deal of ink to be spilt, and with reason.

Indestructibility of the Inter-oceanic Passage.—The "Straits of Panama," that unique artery for the world's commerce, must have as its essential quality—indestructibility in case of war and in case of a grave seismic commotion. The "Straits of Panama," with their width of 600 feet (180 metres) at the water level, their bermes of 100 feet (30·50 metres) on each side, defy all land slips. They need no locks, that plague and constant danger of summit level canals, or of sea-level canals with tidal gates. The only work of art which will exist after the opening of the "Straits" will be the Gamboa dam. But after the construction, this dam will, in reality, have disappeared. The hundreds of millions of cubic yards placed in the valley above the dam will have filled the valley for several kilometres, and this huge deposit will form the veritable and indestructible dam that no explosion of dynamite and no earthquake will be able to affect. Some millions of cubic yards of rock dumps will also have buried the lower face of the dam, rendering it inaccessible and immovable. We may say that the "Panama Straits" will not depend on any work of art, and when once made will have neither locks nor dam.

Nature of the Water-way Created.—It will be a veritable natural road of about the width of the Thames (the width of the Thames at low tide at London Bridge, 650 feet); it will be one-third of the width of the Bosphorus, it will be a water-way where ships will be able to navigate freely, crossing each other as in a large maritime river, with plenty of water on their sides or below their keel. The transit will be made in four or five hours.

Such are the characteristics of this artery, so desirable and so easy to realise if technical blindness did not lead a great nation, like America, to an inconceivable negligence of the clearest and most perfectly demonstrated scientific progresses of our days. By persisting, as she does, in turning her back on progress, and exhausting herself in a useless and ridiculous work, American genius does not see that it is now losing a terrible battle.

The defeat that reason is suffering now in America will weigh heavily on the prestige that American genius had so justly acquired hitherto. It is abjuring at the present day the very doctrine which had made its fame, the increase of machine power and the decrease of the mechanical action of man. We have every right to err as long as scientific truth has not been revealed, but from that moment, to neglect it, to turn our back on it, is to decline. It is lowering one's self willingly in the intellectual hierarchy of humanity.

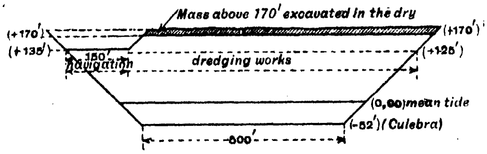
Part II.

Provisional Lock Canal.

The complete solution of the problem, otherwise insoluble, of the enormous labour necessitated by the excavation in the dry, of the Panama sea-level Canal; the possibility of creating veritable "Straits," invulnerable in case of war or earthquake, and that, for an expenditure at the utmost equal to the least costly of the lock canals with a summit level—such are not the only consequences of the substitution of the work on the water or the work in the dry. (Estimates of the Isthmian Committee for a lock-canal with 85 feet altitude, 28,800,000 pounds sterling; Report of 1901. Estimates of expenditure for a sea-level canal, 64,400,000 pounds sterling; document of 1905. Estimates for the Straits of Panama, 30,000,000 pounds sterling.) There is another consequence, likewise a most important one.

During the four to five years necessary for the construction of the dam at Gamboa:—1. If locks be erected at the extremities of the 11 kilometres of the cut of the central mass, and towards the extremity of the maritime parts of the valleys of the Chagres and of the Rio Grande, at the spot that I have indicated as the limits of the two successive dredging levels. 2. If digging in the dry is continued down to elevation 95 feet (28·97 metres) through the passage already opened across the Culebra down to elevation 157 feet (48 metres), a lock canal with a summit level at 130 feet elevation will have been created without great effort, and in a short space of time, between the oceans and at the same time the dredging basins necessary for the execution of the Straits of Panama. (See Fig. C, p. 252, and Fig. D. in Supplement.) The enormous width of the cut will always allow of housing simultaneously vessels in transit, the Lobnitz lock-cutters and the dredges. The transit demands only a band of 150 feet (45·75 metres) and at 130 feet above the sea, the cut will be six times as broad as that and four times as broad at the sea level. It will suffice to insure navigation, at every depression of the water level, to

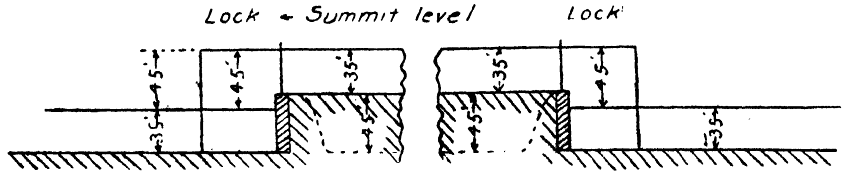
reserve a channel that will have been previously deepened, in order to afford the necessary water depth, notwithstanding the lowering of the water level. The process is so evident and so easy that it is not necessary to dwell on the subject at any length.

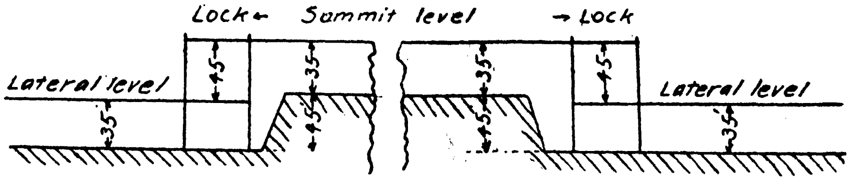


A more serious question remains. What will happen with the locks when the level is lowered? There will be a material impossibility with the usual construction of locks. I have supplied a most simple solution to this problem some twenty years ago. Let us consider a navigable level closed by two locks of the usual type, that is to say, by lock having an upper gate of a height equal to that of the water depth of the level the lock closes, and a lower gate with a height equal to the sum of the water depth and of the fall of the lock.

repeated as many times as is necessary to bring the summit level to the same level as the lateral levels. When the levels of the summit level and the lateral levels are the same, the gates of the lock are taken away. There remains nothing then but the masonry work which is a mass of artificial rock in the new and single summit level, formed by the old summit level and the old lateral levels. This artificial rock is removed as any other rock that is met during the excavation. If the locks are "in flight" by taking dispositions, inspired by the same principle, their gradual elimination is also insured while the transit is going on. It is in this method of construction that the key to the transformation of a lock canal into a sea-level canal resides.

I proposed, in 1887, this method to the old Panama Company in order to secure, in a brief delay, the opening of the canal with locks and to continue later on the excavation of the sea-level canal. I did not then go into the question as far as I am doing to-day. I did not show then the facility for obtaining by this transformation, not only the sea-level canal, but also the "Straits of Panama."





It is evident that with such a lock no lowering of the level is realisable without altering the lock, that is to say, without stopping navigation. But if the upper gate be made with a height equal to that of the lower gate, and if the summit level be deepened on a length of two or three hundred metres above the lock, the entire difficulty vanishes. For instance, one metre of the summit level may be dredged without touching the lock. This deepening accomplished, the level of the water may be lowered one metre without modifying either the circulation of ships or the operation of the lock. This dual operation should be

In those days, only one thing could be guaranteed, namely, that the excavation of the rock of the canal would not cost, if excavated under water, more than in the open air. Now, thanks to the progress made in dredging, thanks to the application of electricity as motor power for the dredges, which I realized for the first time on the River Esla in Spain, in 1895, thanks finally to the progress achieved by the Lobnitz method, in the economic desagregation of rock formation of any hardness, a progress which took place only during the last few years, it is possible to go to the extreme limit of the method and to project the

"Straits of Panama." The great objection to my method of handling the Panama problem has disappeared. The extraction of rock under water already in Europe requires only half the expenditure of its cost in open air. The figures given by the chief engineer of the Manchester Canal, Mr. Hunter, establish it. To the 9d. which the desagregation of the rock costs in the Manchester Canal, if we add 2d. or 3d. for dredging on a large scale, we arrive to a price about half what would cost a similar work in the open air (2s. a cubic yard in the dry). In the Isthmus, this difference increases in enormous proportions on account of the cost and inferior quality of labour, and of the fatal interference of diluvian rains with the works in the dry, especially as far as transport and dumping are concerned, two elements of which the dredging is free.

Opening in Three Years to Limited Shipping or to Military Navigation.—But however rapid the execution of an inter-oceanic passage, at elevation 130 (about four years), this period may be still more shortened, and if, for instance, it was desired to open in three years' time a passage limited to military navigation, it would suffice to add a fifth lock on each side of the Isthmus and to pass in the central cut at an altitude of 170 feet, that is of 52 metres. (See Fig. E. in Supplement.)

The work done by the French companies has, at the present day, opened up a passage at 157 feet, across the central mass, so that it would be sufficient to have only 17 feet excavated on a limited longitude to have the canal bottom at 140 which will give immediate passage. Practically we may say that no excavation of any importance would be necessary in the central mass for that level.

On the other hand, for a lock canal at elevation 170, the erection of the locks may be very much shortened if we limit the masonry to the head of the locks, and if we take the natural slopes of the excavation in their nude state as the lateral walls of the lock, and if we build only one lock instead of turned locks. We would thus reduce to almost nothing the mass of masonry that is necessary for erecting the locks. Of course it would need more water to do the lockages, but this is insignificant—if it is desired to establish military communications only, that is to satisfy a limited traffic.

Finally, whilst constructing the dam at Gamboa, we can, now, provide against the delay of four or five years that it demands, by the installation of pumps to elevate into the summit level the water required for the lockages of the inter-oceanic limited navigation.

One question only remains open in this condensed programme. It consists in the opening of the outlet of the Lake of Bohio. This outlet should be normally made through a saddle between two hills at some distance from the axis of the canal, and may demand two or three years' work. Here, as elsewhere, the problem may be simplified, by making the Chagres flow into the main cut itself, that has been opened for the canal by the old Panama Company. This cut has been excavated through a resisting rocky mass and lowered to 12 metres above the sea. Nothing would be easier than to broaden, in the space of one or two years, this cut, so as to allow the Chagres to flow on the side of the locks installed in the same cut, which will also open up the passage from the Atlantic level to that of the Bohio Lake level.

PART III.

PAST AND PRESENT WORKS AND PROJECTS.

Results of the Work of the French Company.—It will have been seen how the question of opening to traffic may be simplified, if one wants to clear it of an absurd dogmatism and look only at the work to be realised in making use of the great results actually obtained.

The work of the old Panama Company has, in reality, cleared away entirely all the great difficulties of the undertaking. The work of that company has advanced the undertaking to such a point that the rational solution that I have indicated may be applied, and the execution of the "Straits of Panama" may be commenced now with the exclusive employment of natural conditions and natural forces. The work done by that Company if used in a logical way, can allow both the beginning of the construction of the "Straits" and the opening up to traffic, under more or less perfect conditions, according to whether it is decided to devote three years or from four to five years to open the transit. In any case, this premature opening will constitute a most stupendous service to humanity, and the tax of transit will cover entirely the expense involved in the further construction of the "Straits of Panama."

The Fundamental Error of the Consulting Board.—In September, 1905, at Washington, I presented the question of the "Straits of Panama," under a form slightly different from that which I adopt to-day be-

fore the Society of Arts. It was then my desire to show that everything converged towards a rapidly constructed lock canal with a high summit level which should be transformed later on into a veritable Straits. As I have already said, this proposition, "the high level lock canal first, the Straits of Panama afterward," did not gain the day with the Consulting Board, which would not hear of the method of excavation by dredges, and maintained, against all theoretical and experimental evidence, the work in the dry.

This great and deplorable error is the same that was the cause of the decision taken by the Congress of 1879, assembled by M. de Lesseps, in Paris, and by all the Commissions that, successively, have studied the Panama problem. But, contrary to what happened in the Congress of 1879, the Consulting Board was placed in presence of the technical solutions which I brought, and which twenty-six years of progress in the realms of science and industry have rendered so productive in striking results.

As the Congress of 1879 had nothing before it but the work in the dry, that body may be excused for not having seen further; the Consulting Board in 1905 had everything before it, and is without excuse for having closed its eyes. It is not without interest, from a philosophical point of view, to note that the same error generated identical consequences at an interval of 26 years.

In 1879, two projects obtained the preference of the Conference, the project favored by M. de Lesseps, the sea-level canal with tidal locks, and the project elaborated by a great French engineer, Godin de Lépinay. The latter consisted of the construction of dams at the two extremities of the Isthmus, one at 10 kilometres from the Atlantic, at Gatun, across the Chagres, and the other across the valley of the Rio Grande, in the proximity of the Pacific. (While indicating Gatun, Godin de Lépinay reserved the question of the practical possibility of a dam there, and selected Bohio, 14 kilometres higher up, in case the Gatun dam should not prove possible.) These dams would keep the waters of all the rivers of the Isthmus, at 24 metres above the sea ($78\frac{7}{10}$ feet), and would constitute an interior lake, making the Isthmus of Panama an artificial Isthmus of Nicaragua.

Twenty-six years later, two projects identical with those of Lesseps and Godin de Lépinay divided the International Consulting Board at Washington in 1905. The majority, composed of three American and five foreign members*, voted for the sea-level canal with tidal locks; the minority, composed of five American members, voted for a canal with an interior lake formed by a dam at Gatum. The only modification made in the project of Godin de Lépinay was to substitute to the elevation of 24 metres ($78\frac{7}{10}$ feet), the elevation of 25·90 metres (85 feet) for the altitude of the interior lake. No essential characteristic of the project of Godin de Lépinay was, therefore, modified. Alone, his name remained buried in oblivion. (See Fig. A, p. 261, and Fig. B. in Supplement.)

The report of the minority of the Consulting Board makes no mention of the author of the project that it adopted. But the reports of the Congress of 1879 render him the justice that is due to him. It is the project of Godin de Lépinay that met with the favour of the American Government. And it was his project that it recommended to Congress.

Congress was thus placed between two detestable alternatives. The first was to adopt a shallow, narrow sea-level canal, to be dug in the dry, the construction of which could not be effected in less than 20 years, notwithstanding the affirmations devoid of all experimental basis of the majority of the Consulting Board, who solemnly declared that it would require only from 12 to 13 years. The second alternative was to adopt a canal with perpetual locks. This latter solution was introduced to Congress as the American conception, the type of which is the Sault Sainte Marie Canal, by the President of the United States, in opposition to the European conception of the sea-level canal, the type of which is the Suez Canal.

This view is, of course, erroneous; we know that the first lock canal, with a summit level. was built in France, between the Atlantic Ocean and the Mediterranean, by Riquet, under Louis XIV. We know the two great canals of Manchester and of Kiel are lock canals, and, finally, we know the project adopted was a French project, twenty-six years old.

The nationalist argument did not prevail, however, over the evident disadvantages of this system; the terrible accidents to which any false manœuvre would expose it; the

* Majority:—Messrs. George Davis, Barclay Parsons, W. H. Burr (American members); Messrs. W. Henry Hunter, A. D. Guérard, Eugen Tincauzer, E. Quellennec, Welcker (European members). Minority:—Messrs. Alfred Noble, Henry F. Abbott, Frederick P. Stearns, Joseph Ripley, Isham Randolph. (All Americans.)

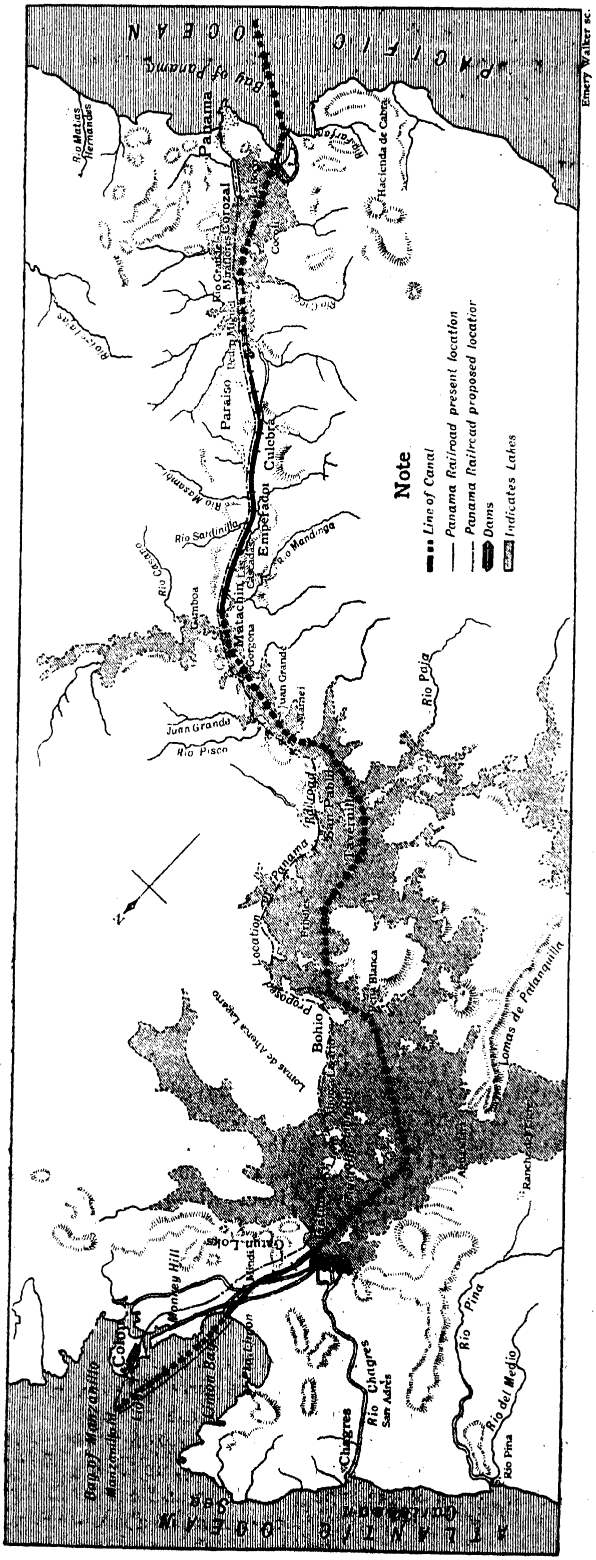


FIG. A.—PLAN OF THE PANAMA HIGH-LEVEL LOCK CANAL (summit elevation 85'). (See Appendix, p. 270.)

danger of destruction in case of war or of seismic commotion; without counting the compulsory limitation to traffic owing to the limited quantity of water from the rivers that feed it (58,000,000 to 96,000,000 tons, according to the futute average size of the ships).

That project was defended with tenacity by the Government, and even represented as superior to the sea-level canal. Such a theory is as vain as that of the surgeon trying to demonstrate that a wooden leg is superior to a natural leg, and it did not convince the American Senate.

Then, in order to save the project, it was thought necessary to return to my proposition, and Senator Knox, in a speech that decided the battle, showed that the proposed lock canal would later on be transformed into a "true sea-level canal," a canal from 500 to 600 feet wide and 50 feet deep; that is the type of water-way I had proposed and called the "Straits of Panama." The project was adopted.

It seems at first glance indifferent whether the first form of the lock canal be realised with a summit level of 85 feet, or with a summit level of 130 feet above the ocean, if precautions are taken to ensure the ulterior transformation into veritable straits. Nevertheless, it is wholly different. The cut to be made in the dry is 53 million cubic yards for an 85 feet summit level, whereas it is only 20 milllons for the summit level of 130 feet. Besides, if this summit level is but a preliminary phase, an opening may be made with a narrower passage requiring only 12 million cubic yards. The widening would immediately follow the opening. Now, if 3 million cubic yards can be excavated annually, as it is proved, it will require 4 years for the passage at 130 feet, and 17½ years for the complete cut, made in the dry, and necessary for the passage at 85 feet.

This example shows the radical difference in opening the cut for a provisory summit level at 130, or for a definitive summit level at 85. Of course, great exertions may and will reduce the term of 17½ years, but these efforts are wasted in a struggle against nature to obtain finally an inferior solution, much more difficult to transform into a sea-level passage than a higher lock canal.

It is not without interest to examine the consequences that have already taken place, of the great error committed by the American Government in the final selection of the type of the canal.

Present Condition of the Work done by the American Government.—On March 3rd, 1881, the Universal Company of the Panama Canal was formed, and in November, 1883, the final plans were approved. We may take it for granted that one year and ten months were spent in studying, in boring, in clearing the virgin forest, in transporting the first plant, in building the houses and hospitals, and—in a word—in organising life and work in what had hitherto been wilderness. Three years after the beginning of actual works, by the 1st January, 1886, about 15,000,000 cubic metres (20,000,000 cubic yards) had been excavated. The totality of the constructions then covered a surface of 217,184 square metres (260,000 square yards), that is to say, a surface equal to that of a band extending along the canal from one ocean to the other, 3·2 metres or 10·5 feet in width. These constructions have since then been very much increased, and now cover a still larger area.

On January 31st, 1886, while I was chief engineer of the company, I had the honour of exceeding in the quantity of work executed, the total of 1,000,000 cubic metres per month (which for a long time had been aimed at), and of producing 1,067,823 cubic metres (1,397,000 cubic yards), during the month of January. The work was interrupted at the end of 1888; the total cubic volume executed by the Lesseps company amounted then to 72,000,000 cubic yards—the official figure furnished by the Isthmian Canal Commission in its reports of 1901 and 1906—which corresponds to an average cubic monthly output of 1,000,000 cubic yards during the six years of effective work. To this figure must be added about 8,000,000 cubic yards, executed by the new Panama Canal Company, between 1894 and 1904, the year when the American Government purchased the canal.

The value of this immense quantity of works, installations and plant, was estimated by the Isthmian Canal Commission, in round figures, at 33,000,000 dollars, that is £6,600,000 sterling, or 165,000,000 francs. It may be added, however, that the Commission only took into account 39,586,332 cubic yards as the sole part of the excavation that could be utilised in the execution of the plans it had adopted.

Since the recommencement of the work by the American Government, that is to say since April 1904, up to the end of 1906, the amount of the ground extracted for the excavation of the canal is about four million cubic yards.

In addition, dredgings have been executed at Panama and at Colon, but they have been done rather with the object of keeping in order the present installations. The total sum spent by the American Government in installations and work, up to the end of 1906, amounts to about 40,000,000 dollars (£8,000,000), that is to say to seven million dollars more than was paid to the French Company for their works, plant, and installations, according to the American estimates. The Isthmian Canal Commission certainly believed that it would produce a similar quantity of work, plant, and installations for an equal sum. We see now that with a much higher expenditure, four million cubic yards are excavated within about three years instead of 72,000,000 within six years. It would not be correct to suppose that the buildings, hospitals, and shops were no longer fit for use, and that new constructions had replaced them. The report of the Chief Engineer, Mr. Stevens, established on June 30th, 1906, the following statistics on the present distribution of the dwelling places :—

White married quarters—	
Built by the French	235
,, ,, Americans	73
Coloured married quarters—	
Built by the French	297
,, ,, Americans	20
White bachelor quarters—	
Built by the French	163
,, ,, Americans	12

It must be added that the work accomplished by the Americans in the sanitation is deserving of the highest praise. They have reproduced in Panama what they so perfectly did in Cuba five years ago. It is based on the application of the theory of Carlos Finlay, the Havana doctor, who discovered the origin of yellow fever a quarter of a century ago, and was not listened to until the admirable experiments of the American physicians demonstrated that it was true. But this work of prophylaxy consists especially in a rigorous sanitary police and does not require heavy sacrifices of money, nor the employment of a very great number of men. It has not interfered with the works of excavation proper. However, the success in stamping out yellow fever caused by the stygomia, a house mosquito, did not crown the efforts made against malaria, caused by the anopheles, a marsh mosquito.

During the first two years the small results of the works were explained by the need of a systematic organisation. "We have made 240,000 cubic yards in April," said Secretary Taft before a Committee of the House on May 24th, 1906, "but we have not begun yet, we are just ready to begin." In April Mr. Shonts in a report to the Secretary of War (Mr. Taft) wrote that a 1,000,000 cubic yards monthly excavation would be obtained from July on, but the maximum reached ever since was 325,000 cubic yards. Up to the present day the American Government has met only with bitter surprises.

PART IV.

CONCLUSION.

The general cause of the specified failure suffered by the Americans in the execution of the work and in the selection of the elevation of the first navigable summit level (not to speak of the unseemly error to dam the Chagres at Gatun), is due to their ignorance of the injurious influence of the rains on the excavation in the dry in the tropics. They have overlooked this essential element, which is the key to the whole situation, and they have refused to take into account the necessary system of excavation on water which appeared to me as the final teaching of the bitter experiences of the old Panama Company.

The Americans thought that by increasing the size of excavators, of cars, of locomotives, the cubature excavated would increase proportionally; but the contrary proved to be the case, as was to be expected.

A short extract from the message of President Roosevelt of December 17th, 1906, clearly brings out the fact :—

"The implements of French excavating machinery, though of excellent construction, look like the veriest toys when compared with these new steam shovels, just as the French dumping cars seem like toy cars when compared with the long train of huge cars dumped by steam ploughs which are now in use."

A little further on he says :—

"In the rainy season the steam shovels can do but little in dirt, but they work steadily in rock or in the harder ground."

President Roosevelt might say of the huge cars what he says of the steam shovels and add that, over the lines of the earth excavation works, these cars are permanently off the rails and not on them. (See Fig. G., p. 264 for the American plant, and Fig. K., p. 244 for the French plant.)

If the old Panama Company had committed the unpardonable mistake of measuring the weight of the locomotives and cars, according to the importance of the cut, and not according to the conditions resulting from the

G.—AMERICAN SHOVEL AT WORK. (See Appendix, p. 272.)

ground and from the rain combined, if it had chosen the present American plant, it would have done absolutely nothing during nine months out of twelve. In fact, the President tells us that this plant accomplishes nothing in the soft ground during the rains, and almost the whole of the cuts, at the time of the French works, were in ordinary clay, not in rock or hard clay, as are the Americans now, thanks to the low level reached by the French excavations. Certainly the American engineers did not take these facts sufficiently into account, or they would have hesitated to compare to toys the plant which, 20 years ago, excavated, with fewer men than they themselves now employ, 1,400,000 cubic yards per month, in a much more difficult ground than they have now, while the so-called perfected machinery which they use, only yield them a record of 325,000 cubic yards per month (October, 1906). This is less than one-third of the volume officially announced last April by the President of the Isthmian Commission, as that which would characterise the monthly excavation for the second half of 1906 (1,000,000 cubic yards).

For the excavation of the high parts of the mountains, for the enormous and necessary work which they have accomplished, the French engineers have, therefore, acted wisely in choosing the locomotives of 30 tons and the cars carrying 10 tons of ground, which the Americans disdainfully call "toys." The enormous work accomplished by the French engineers under such difficult circumstances, the inability of their successors to attain—even approximately—the results which they achieved, largely compensate for the slight ridicule which is mingled with the accusation cast at them—that of having employed toys for this great battle with nature. The value of weapons—like that of tools—is not to be measured by their weight, but by their efficiency.

I have established that now, at this present stage of the work, dredges and barges should be substituted for the early plant which was necessary and well determined in the first period, and not heavier locomotives or steam-shovels.

It was at the commencement of this new phase that the Panama Canal came into the possession of America. The American engineers either did not know or would not understand, the marvellous facilities which this new period offered them if the proper method was used. Either they did not know or would not understand, the philosophy of this great problem, and how the way was opened up before them to realize in four years a lock canal communication between the oceans, and eleven years later the immortal and generous creation of the "Straits of Panama." Is it too late for a reaction? No, if the great question were examined in a purely scientific spirit. Yes, if national vanity steps in.

At one time it seemed as if President Roosevelt wished to exclude all narrow national tendencies from the scientific search for the best solution. This was when, in April, 1904, he decided to ask the English, French, German, and Dutch Governnments to appoint technical delegates to the Consulting Board, who had to decide on the best plan.

Unfortunately the question again entered into the sphere of petty national considerations, when several months later the President of the United States, on the 13th February, 1906, wrote in his message to Congress recommending the permanent lock canal:—"It will be noticed that the American engineers on the Consulting Board and on the Commission by a more than two to one majority favour the lock plan, whereas the foreign engineers are a unit against it."

Scientific truth is neither English, American, French, German, nor Dutch; it is the scientific truth, and belongs to the whole human race. No doubt each branch of the human race may pride itself on having helped in the establishment of such truth, but to be limited by the geographical boundaries of countries in the search after truth is to stray into voluntary error. This error was committed by President Roosevelt when he recommended the canal with permanent locks as being the American solution.

The monstrosity of placing permanently the future of the commerce of half a continent and the military security of the United States in a project which would be constantly menaced by accidents or earthquakes so impressed the Senate that the Senatorial Commission of the Isthmian Canal rejected the presidential recommendation. The Senate was about to act in a similar manner, when, at the last moment, Senator Knox, on June 19, 1906, saved the proposition, as we have seen already, by depriving it of its characteristic of perpetuity, and by accepting my formula, "the high-level canal first; the Straits of Panama afterwards."

He said: "Because the lock type of canal can, if necessity ever arises, be transformed

Fig. H.—View of an Excavation in the Culebra Cut (see Appendix, p. 273.)

into a true sea-level canal, one of five to six hundred feet in width, and fifty feet or more in depth of water." It was my proposition in its general terms; it caused the Senate to rally, and the canal with locks was accepted. But the form thus adopted for the first stage of the construction of the Straits of Panama, had to bear the consequences of the error which presided at its conception. It comprises an unnecessarily deep cut to be dug in the dry, and a needlessly wide and dangerous dam across the Chagres at Gatun.

President Roosevelt, notwithstanding the optimistic tone of his message of the 17th December last, owned that this dam, an earthwork with a length of 7,700 feet, and holding water at 108 feet above the bottom of the bed of the river, would entail "some little risk." This is a serious expression coming from the lips of the head of a country when speaking of the keystone of the vast enterprise to be undertaken. The successive consequences of the initial error committed in the conception of the project are manifest in the carrying out of the work. The President in his message speaks of the record breaking excavation of 325,000 cubic yards of October. He does not remark that it represents less than one-third of what his engineers expected to follow immediately the end of the period of organisation. The President is also bound to inform Congress that in April next the location of the locks will be finally settled. This is to admit that the locks are badly placed, that suitable sites are being still sought for and that, therefore, the final plan of the Government has not withstood the test of the first experimental works.

All these material facts and the enormous sums of money (£8,000,000 or 40,000,000 dols.) spent in two years and eight months without producing any serious results, should sound the alarm and show that the wrong track is being followed, and this mournful road leads to a dangerous and uncertain plan, which will, perhaps, replace the inauguration fêtes by a fearful cataclysm. Heroic courage is certainly needed in order to return to the truth, and if there be a man capable of showing this it is President Roosevelt. His latest message, however, does not seem to indicate that we may hope for it. Confidence obviously inspires the President in spite of these facts. That it is not well placed is sufficiently indicated by the photograph which we extract from his message with the inscription placed below. The President has obviously been deceived into believing that a new level 65 feet below the one created by the French had been dug through the entire Culébra cut seven miles long. The excavation referred to is simply the removal of an embankment 200 metres wide, 35 feet high, left across the cut opened by the French for the passage of trains. (See Fig. H., p. 266 and Explanatory note, p. 273.)

Except for this removal there has been no substantial change whatever in the general level created by the French. The amount of excavation done by the Americans is obviously too small to have permitted the creation of a new level 65 feet lower than the one existing when they took possession or even anything approaching it.

I am deeply distressed about this, for I had ardently desired that the work undertaken by the United States at Panama might add to their glory and not turn into a source of regrets and sorrows. I have done everything in my power to show the right path.

For years I have combatted in the United States the erroneous solution of the Nicaragua Canal, which, for half a century had been supported by the unanimous scientific and political votes of the Americans. I have triumphed over this legend, thanks to the constant help and to the boundless devotion of two great American citizens, Mr. John Bigelow and Senator Mark Hanna, who knew how to place national interest higher than national vanity, and to bow before scientific truth without regard to the nationality of those who struggled to attain it.

Later, when Colombia wanted to oppose the resurrection of the Panama undertaking, I co-operated in the work of the Isthmian secession, and as Minister Plenipotentiary of the new Republic, I signed, with the Secretary of State, Mr. Hay, the treaty between the two Republics by which the Panama Canal was born out of its own ashes.

I have again met in the person of Mr. John Hay, the noblest and purest-hearted of men; and the great Trans-Atlantic Republic, in losing Mark Hanna and John Hay, has also lost the sincere counsel of the noblest patriotism. They were no longer the councillors of the Government when I accomplished the third part of my task, when I brought forward the dearly-bought experience acquired by the old Panama Company. I showed how the work should be executed and what should be the object aimed at: the "Straits of Panama"—which might easily be completed in 15 years, after having opened a passage in four years or even less. I have spoken to the

FIG. F.—INSTALLATION OF DREDGING WORKS MADE AT CULEBRA (1888). (See Appendix, p. 272.)

FIG. L.—RESERVOIR ON THE HIGH RIO GRANDE (1888). (see Appendix, p. 273.)

blind, who would not see; to the deaf who would not hear. Apparently what was wanted was something American, and what I brought forward was not American, though it was inspired by the American system of labour-saving appliances. The un-American system of labour-wasting appliances was considered for the first time as typical American.

Mr. Lindon Bates, a well-known American engineer, described this phase in a recent work ("The Crisis at Panama"):—

"When, three years ago, our Government took over the enterprise of the Panama Canal, it was with its proverbial enthusiasm. Our self-confidence was boundless. We would exhibit to the world how competent American business methods would put the water-way through. We had a subtle disdain for our predecessors—the impractical French. We tinctured in with pity: the visionaries. So we bought all their properties, channel right of way, railroad, charts, machines, scrap-heaps, and smiled, for we believed we had driven a Yankee bargain.

"One thing was overlooked, and the French, with idealistic generosity, threw it in. It had cost them six times what we were giving for their whole investment. Yet truly for us it was, of all, the most valuable asset —their experience. Had we bought it at a high price it might have been prized and have been let yield us precious saving service.

"But it too has been disdained, and in blind obliviousness, we head the old fateful way into the self-same pit.

"Labourers are wanted at Panama; the call has gone out from the Isthmus for fifty years.

"In the closing months of the French regime light dawned, and the word went forth—the minimum of men, the maximum of water-borne machines and land plant invincible to rain. This was the final dictum of a generation's experimenting." See Fig. F., p. 268, and Fig. L., p. 269.)

However this may be, I have done my duty as a sincere friend of the United States, and have endeavoured to point out to their engineers the road to be followed. At the same time—and this was my principal object—I have done my duty to my own country in showing that its engineers from the very beginning were equal to the great task which they had undertaken; in showing that our intellectual patrimony may claim the honour of having found the solution of the problem set by Charles the Fifth in 1523 to Cortes: Discover the Secret of the Straits (*el Secreto del Estrecho*).

This secret, as I have shown, is henceforth brought to light. It does not lie, as Cortes and his successors imagined, in the geography of the Isthmus, but in its topography and in its hydraulics. Everything has been prepared by nature for hydraulic power to lift, in the high valley of the Chagres, the earth and the rocks which obstruct the site of the Straits. Harness this power, and the Straits will be made by its spontaneous action. This is the "Secret of the Straits."

APPENDIX.

EXPLANATORY NOTES, FIGURES A. TO M.

A.—*Plan of the Panama High-level Lock Canal (summit elevation, 85') adopted by the American Government.* (Original project of Godin de Lépinay, 1879). (See p. 261.)

NOTE.—Godin de Lépinay had indicated the Gatun location for the dam in his plan, under the reserve that it would be recognised a possibility there; he said that in the contrary case the location ought to be Bohio, 9 miles up the river (14 kilometres).

The only reason which actuated the American minority of the Consulting Board in choosing Gatun, which always had been condemned ever since Lépinay mentioned it as a location for a dam, must be attributed to their great desire to prolong as much as possible the limit of exploitability of a lock canal. This limit is fixed by the minimum average yearly output of the rivers feeding the summit. This limit corresponds at Bohio to a transit of 40 to 60 million tons. As the Sault Sainte Marie Canal has already reached 44,000,000 tons traffic, a lock canal at Panama with the limit corresponding to the Bohio dam, could not be called but a temporary solution in America. With a dam at Gatun the water output is half greater than at Bohio, and the limit of exploitability is from 60 to 100 million tons. This enabled the minority to dispose of the objection which any lock canal at Panama finds, its narrow future. They even tried to go further and said the limit could be extended with more dams—this is erroneous, more dams do not give more rain.

B.—*Longitudinal Section of the Panama High-Level Lock Canal (summit elevation, 85') adopted by the American Government in* 1906. (Original project of Godin de Lépinay, 1879). (See Supplement.)

NOTE.—This project, recommended by the minority of the Consulting Board as the perpetual solution of the Panama problem, was endorsed by the American Government and proposed to the Congress of the United States (February 19, 1906). It was voted down by the majority of the Senatorial Isthmian Canal Committee, but was finally adopted by the Senate (June 21, 1906) on the strength of Senator Knox's declaration that it could be transformed "into a true sea-level canal, one of 500 to 600 feet in width, and of 50 feet or more depth of water," that is to say, into the "Straits of Panama" (Bunau-Varilla project, 1905).

The vital objections to this very bad solution is (1) The magnitude of the summit level cut to be excavated in the dry (53,000,000 cubic yards); (2) The erection at Gatun of a huge, dangerous, and badly-located earth dam, 7,700 feet long, of 21,000,000 cubic yards volume, holding the water 85 feet above sea-level, across a river, the bed of which is 22 feet below sea-level. The method of construction is the one proposed by Mr. Bunau-Varilla for the small and low dam at Bohio and consists in depositing dredged soil by means of centrifugal pumps. The ground, excellent at Bohio, is unfit between Gatun and the sea, being largely marshy silt incapable of settling; (3) The advantages offered by dredging in the transformations of a high-level canal diminish when the snmmit is lower, and more ground must be excavated in the dry above the level of work of the dredges; (4) The location of the locks in this plan are in a bad ground, and the site chosen has proved inadequate.

The longitudinal profile of the Panama Route shows:—

1st. The original natural ground along the axis of the canal.

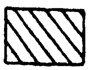
2nd. The lowest point reached by the excavation in every cross-section. (Between this lowest point and the original natural ground the cut is entirely open, but necessitates in most places widening.)

3rd. The water-level and bottom line of the High-level Lock Canal (85'), the location of locks and dams.

4th. The mean water-lever and the bottom line of the Straits of Panama.

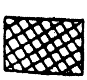
Excavation actually made by the French companies —60,000,000 cubic metres or 80,000,000 cubic yards,

approximately (including deviations), (of which about 9-10ths resulted from the works of the old Panama Company, and 1-10th from those of the new Panama Company), the works of the old company having been accomplished within eight years, including more than two years for the first surveys, the opening of the country, the transportation of a plant worth 30,000,000 dol., the erection of houses and hospitals, &c., leaving between five and six years for the works proper, now represented by an excavation of 55,000,000 cubic metres, or 72,000,000 cubic yards.



Excavation to be made to open the High-level (85') Lock Canal (bottom width 200', water depth 42') — total excavation through the central mass, 53,800,000 cubic yards.

Excavation to be made for the transformation, without any interruption of transit, by floating



dredges of the High-level Lock Canal (85') into the Straits of Panama. Bottom width 500', water depth 45' at the lowest tides)—457,00,0000 cubic metres, or 600,000,000 cubic yards (including the volume of excavation of the High-level Lock Canal).

Such excavation would be reduced to 156,000,000 cubic metres, or 205,000,000 cubic yards, if the transformation would simply aim at the creation of the narrow, shallow, Tide Locked Sea-level Canal, usually termed the Sea-Level Canal, which, if constructed immediately by the usual methods of excavation, steam shovels on rail, and railroad transportation of the spoils to the dumps, would require for the opening of transit a period of time about equal to the sum of the two periods necessary first for building the High-level Lock Canal, and second, for transforming it into the Straits of Panama.

C.—*Plan of the Panama High-level Lock Canal (summit elevation 130'). Constructible in four years (first phase) in order to be later transformed into the "Straits of Panama" (second phase) without interfering with navigation.* (Bunau-Varilla project of 1905). (See p. 252.)

NOTE.—This plan is the same as for the lock canal at elevation 170', only two more locks have to be added. It has appeared unnecessary to make a special plan for the particular project, the location of the locks being shown in the longitudinal sections.

D.—*Longitudinal Section of the Panama High-level Lock Canal (summit elevation 130'). Constructible in four years (first phase) in order to be later transformed into the "Straits of Panama" (second phase) without interfering with navigation.* (Bunau-Varilla project of 1905). (See Supplement.)

NOTE.—The governing ideas of the conception of the high-level lock canal at elevation 130' is 1st, to reduce to the minimum the amount of excavation of the central cut so as to be sure to dispose of it in 4 years, without too much elevating however the summit. 2nd, to reduce as much as possible the height of the dam at Bohio. In this plan the head of water is reduced to a maximum of 60' above the sea, the level of the ground of the valley being 30' above the sea, and the bed of the river being at sea-level.

The method proposed by M. Bunau-Varilla for erecting this easy dam and which was so unhappily applicated by the minority of the Consulting Board for the Gatun dam, consists in bringing, in scows, dredged material from the neighbourhood to the site of the dam and to pump it on the dam location. The ground is excellent at Bohio, very bad at Gatun. The length of the dam at Bohio (1285' at the crest) is about six times smaller than at Gatun, and its height above the bed about half the height of the Gatun dam. 3rd, the lock canal being temporary the locks can be smaller than in a perpetual lock canal.

The longitudinal profile of the Panama route shows:—

1st. The original natural ground along the axis of the canal.

2nd. The lowest point reached by the excavation in every cross-section. (Between this lowest point and the original natural ground the cut is entirely open, but necessitates in most places widening.)

3rd. The water level and bottom line of the High-level Lock Canal (130'), the location of locks and dams.

4th. The mean water-level and the bottom line of the Straits of Panama.

Excavation actually made by the French Companies.

(See note to Diagram B.)

Excavation to be made in four years to open the High-level (130') Lock Canal (bottom width 150'—water depth 35')—total 45,000,000 cubic metres or 60,000,000 cubic yards approximately, of which 20,000,000 cubic yards only are to be excavated in the central cut, making necessary a total yearly output (15,000,000 cubic yards), inferior to that reached by the old company (16,000,000 cubic yards).

Excavation to be made for the transformation, hout any interruption of transit, by floating dredges of the High-level Lock Canal (130') into the Straits of Panama, (Bottom width 500', water depth (45' at the lowest tides)—457,000 cubic meter. or 600,000,000 cubic yards (including the volume of excavation of the High-level Lock Canal).

E.—*Longitudinal Section of the Panama High-Level Lock Canal (summit elevation, 170'), constructible in three years for a limited traffic such as that of military navigation, in order to be later transformed into the "Straits of Panama," without interfering with navigation.* (See Supplement.)

NOTE.—It is the Bunau-Varilla project of 1905 modified in view of reducing to the lowest limit the works necessary to the opening of interoceanic communication, and therefore the time necessary.

The governing ideas of this project are the following:—1st. In order to eliminate the time necessary to open a cut through the summit, the water is raised high enough to form a continuous level which dredges will widen and deepen, or to reduce the work in the dry to an insignificant amount if it is thought preferable to dig during the erection of the locks. 2nd. In order to eliminate the major part of the time necessary for the masonry of the locks, it will be limited to the heads of these works, the slopes of the cuts will limit laterally the body of the locks. 3rd. The outlet of Lake Bohio will be opened through the canal cut laterally to the locks. 4th. The locks will be single and sufficient for the largest men-of-war. 5th. In order not to wait until the dam at Gamboa is erected, a steam pumping-station will be established near Gamboa to feed the summit level for the limited traffic referred to during the dry season, and help the Obispo River during the wet one.

This conception would correspond to the opening of navigation for military purposes during the executions of the Straits of Panama by dredging, and would greatly facilitate the works by giving free access to the plant from the sea to the summit level.

The longitudinal profile of the Panama route shows:—

1st. The original natural ground along the axis of the canal.

2nd. The lowest point reached by the excavation in every cross-section. (Between this lowest point and the original natural ground the cut is entirely open, but necessitates in most places widening.)

3rd. The water-level and bottom line of the High-level Lock Canal (170'), the location of locks and dams.

4th. The mean water-level and the bottom line of the Straits of Panama.

Excavation actually made by the French companies.

(See note to Diagram B.)

Excavation to be made in three years to open the High-level (170') Lock Canal (bottom width 150', water depth 35').

Excavation to be made in 10½ years for the transformation, without any interruption of transit, by floating dredges of the High-level Lock Canal (170') into the Straits of Panama. (Bottom width 500,' water depth 45' at the lowest tides)—450,000,000 cubic metres or 600,000,000 cubic yards (including the volume of excavation of the High-level Lock Canal.)

F. — *Installation of Dredging Works made at Culebra (Pacific slope) in* 1888 *by M. Bunau-Varilla, about* 18 *metres,* 60 *feet above the Rio Grande river.* (See p. 268.)

NOTE.—Owing to the lack of water communications, which then were not easy to establish with the projected Lake of Gamboa, the spoils were then dredged again and sluiced into the Rio Grande valley. This was temporary. It was intended to remove by railroad transportation the redredged material until the water communication could be established with the Gamboa Lake. This precious installation was blindly abandoned by the new Panama Company and the floating plant put aside. It astonished very much the American engineers to find naval plant on the top of the Culebra cut. "What man does not understand," said Goethe, "he makes fun of." The Secretary of War, Taft, materialized this thought of Goethe when he said to a Committee of the House: "Mr. Stevens, the Chief Engineer, has got a launch which was found on the top of the Culebra cut, that he took down from there, and had repaired, and is now using at La Boca. They (meaning the French) apparently thought the water was coming up the top of the cut and they would get the launch there in time."

G.—*American Steam Shovel At Work.*

It is to this type of steam shovels that the American opinions attributed erroneously the future solution of all excavation problems. (See p. 264.)

The American engineers have been led to recog-

nise that the difficulties of the Isthmus are entirely in the transportation, and not in the loading of the material. (This photograph is extracted from the message of the President of the United States, December 17th, 1906).

H.—*View of an Excavation in the Culebra Cut.* (See p. 266.)

NOTE.—This picture is extracted from the Panama message sent to Congress on the 17th of December, 1906, by President Roosevelt, on his return from the Isthmus.

This picture appears in the message with this line below: "View in Culebra Cut. The level at which the two men are standing is that reached by the French; the level at which the motor-car stands is the present American level—65 feet below."

Everybody reading the message cannot help believing that a new level 65 feet below the lowest, left by the French across the Culebra Cut (seven miles long) has been excavated by the Americans.

There is, unfortunately, not the shadow of a reality in such a belief which the line below the picture above necessarily creates. President Roosevelt must have been deceived by some false explanation, otherwise he would not have inserted such a statement in a public document bearing his respected name.

For the necessities of railway communications, the Panama Company had left a short mass of ground (200 to 300 yards long) 33 feet above the general level they created at 157 feet (48 metres) through the Culebra Mass, originally 333 feet high above the seaon the axis, and 300 at the lowest point of the saddle. This small mass of ground has been removed by the Americans. It has the importance of the removal of a railway embankment. It is not the creation of a new level. Nothing else can give the colour of reality to the phrase reproduced above. The report of the Isthmian Canal Commission for the year ending December 1st, 1906, says:—"The engineering work of the year has been almost entirely preparatory. . . . . . The general plan of the work which has been done in the Culebra Cut has been in putting the various levels in proper conditions for the maximum number of steam shovels." Such capital work, then, as the creation of a new level 65 feet below the level reached by the French, has never been made.

I.—*Twelve-ton Lobnitz Rock Cutter working in the Manchester Ship Canal,* (from *Engineering*, August 17th, 1906, kindly lent by the editor of *Engineering*). (See p. 248).

NOTE.—The average cost in ten months, of operating this machine for loosening the rock and transforming it into a material as easily dredgable as sand was 8·94 pence per cubic yard in spite of the interruptions of the works by the ships. (Figures given by Mr. Hunter, chief engineer of the Manchester Ship Canal.)

J.—*Comparative Cross Sections.* (See p. 240.)

The hulls represented in the drawings above are those of the new Cunarders, *Mauritania* and *Lusitania*. Their beam is 88 feet, their draught of water 36 feet. They would pass the "Straits of Panama" with 9 feet below the keel at the lowest stages of the tide, and with ample room to cross each other. They could not pass the Panama sea-level canal for want of depth, and they could not cross each other if they had the necessary depth. This was partly remedied by the Consulting Board. The majority gave 40 feet depth, and the minority 42 to 45 feet depth to the canal. In both cases the cut at Culebra, 200 feet wide, does not allow the crossing of such ships.

NOTE.—The two cross sections correspond to the average altitude of the ground on the axis in the Culebra cut, 181′ $\frac{7}{10}$ (55 m. 43.). The depth of water in the "Straits of Panama" is the average depth at mean tide in the Culebra cut.

The time of construction by wet process of the "Straits of Panama" is estimated at 15 years, the expenditure is estimated at £30,000,000. The excavation is estimated at 600,000,000 cubic yards.

The time of construction by dry process of the "sea-level canal" is estimated at 22 years, the expenditure is estimated at £60,000,000 by the Isthmian Canal Commission, the excavation is estimated at 205,000,000 cubic yards.

K.—*Works in the dry (Culebra) as they were installed in* 1888 *(looking towards Panama) by the old Panama Company (de Lesseps Company).* (See p. 244.)

L.—*Reservoir on the high Rio Grande, created in* 1888 *by M. Bunau-Varilla for feeding the dredging pond he installed on the slope (Pacific side) of the Culebra Saddle, and which is represented in drawing F.* (See p. 269.)

This reservoir has been used by the Americans 16 years later to feed the town of Panama with drinkable water.

M.—*Works in the wet. Dredge working in Blasted Rock,* 1888. (See p. 245.)

NOTE.—After M. Bunau-Varilla removed in 1885 rock under water at a moderate price (8 francs a.c.m.), the contractor in charge of the Mindi Hills preferred drowning the open-air excavation in the rock and attack it by dredge, after mining and blasting it either above or below water. This shows that already in 1887 it was deemed more economical to mine under water the rock and to dredge it, than to excavate and to transport it in the dry. Now, with the electric and large dredges with the Lobnitz cutters, this is ten times more true.

DISCUSSION.

The CHAIRMAN, in opening the discussion, referred to the fact that the author had been connected with the Panama Canal since 1884, at which time he was in co-operation with M. de Lesseps, who was the

prime mover in the starting of the great scheme. The audience therefore had had the pleasure of listening to a gentleman who had had more than usual opportunities of making himself acquainted with the project in general and with the special difficulties which had to be surmounted. All had listened to the author's description of the Panama Canal and the problem which had to be solved with very great interest, and felt that he had given his whole heart to the solution of the problem of the secret of the Straits. The author was an entirely independent gentleman so far as the present undertaking was concerned, and he had come that evening to give to the Society, and through the Society to the world, his well-considered views as to the proper mode, and, in his opinion, the only mode, of bringing the work to a successful issue. He (the Chairman) was afraid that, without more study than one could give to a subject which was abstruse, it was very difficult to express any opinion on the author's views, but in principle one could not help being captivated with the idea that the work could be constructed and brought to a proper issue by the use of water as the carrying power for the machinery to do the excavation, and as the carrying power for the transport of the dredged material to its destination. One could not help being struck also with the great ingenuity by which a large receptive place could be made where the dredged material might be deposited, at a level which was sufficiently convenient for the barges to reach. The mode of carrying out the work as described by the author, the number of barges which would have to be employed, the number and the size of locks which would be necessary in order to perform the work in any given time, and the quantity of material which would have to be transported were matters of careful calculation for the engineers, with which the present meeting had nothing to do. The broad principle commended itself to an engineer at once, that if it was possible to use the flotation power of water to bring the excavators to the place where the excavation had to be made, and if it was also possible to take the barges from the dredger to the place for which they were destined, it would solve some of the greatest difficulties of dealing with such a work in such a country. As the author said, instead of treating the great rainfall as an enemy, he converted it into a friend and an ally; and if that plan could be carried out, it seemed to him a most valuable suggestion. His own experience went to corroborate these views entirely, because he very well knew the cost of excavating in waterlogged strata when the excavation was made in the dry, where the rain caused innumerable slips of earthwork and occasioned the greatest difficulty in maintaining the roads. If these difficulties could be avoided, an enormous amount of trouble was done away with, and a price was reached which was far and away less than anything which could be contemplated for excavation in the dry. He supposed one might almost say that the Suez Canal would have been impossible of construction if it had not been for the great improvement in dredging plant which took place about the time that the problem had to be undertaken, although in that instance the distances to which the earth had to be transported were comparatively short. Since that time the development of dredging plant had gone on by leaps and bounds, and engineers were now able to use dredgers supported by water at the spot where the work had to be done of a power and celerity of excavation which were never dreamed of in former years. All those developments had taken place within the memory of those present, and they were not yet at an end. The only point which struck him adversely in the paper was where the author talked of excavating with dredgers which were 16 years old. He thought the author in that instance could only have been referring to an experimental excavation because personally he should be very sorry to undertake to go on with the Panama Canal with dredgers built 16 years ago when he could now obtain dredgers of a very superior character and of much greater power. He had had something to do with the Suez Canal, and could speak from experience with regard to the question of the excavation of rock under water. Mr. Quellennec the consulting engineer of the canal, knew the price of the work much better than he did, but the matter was brought before him while he was a member of the International Consultation Commission on the Suez Canal. It was at one time considered that the excavation of the rock between the Bitter Lakes and Suez for the purpose of deepening the canal to suit the modern requirements of ships presented such a serious obstacle that the work was suspended for many years, although everybody knew it would have to be done. But that difficulty disappeared. The work was done without explosives, the traffic of the canal was not interrupted, and the price at which the excavation of the rock under water was done was given by Mr. Quellennec at 1s. a yard. Mr. Hunter had also stated that he excavated the rock in the Manchester Canal under water by the same Lobnitz process at 9d. per cubic yard; and those prices engineers must take as facts. Taking those prices as true (and they must be so considered on the evidence of such eminent engineers) it did seem a very startling proposition that engineers should be contemplating at the present time such a very large price for the Panama Canal as 10s. a cubic yard for rock excavation. He also desired to say that he could, more or less, corroborate from his own knowledge the prices the author had quoted for the dredging of soft material. He had excavated and removed to a distance many millions of yards of such material; and in addition to that engineers were now, under more modern principles, excavating material and pumping it for half a mile or 1½ miles through large pipes without the least difficulty and at a very moderate price. That again showed how very much could be learned when one had to deal with a dredging system compared with an excavation system. The grandeur of

the author's conception struck him at once as one which all would like to see completely considered. Although the cross section of Panama Canal, as proposed by the Commision, was much larger than the Suez Canal, it was comparatively small in view of the constant augmentation of the size of ships, and he thought it would be found that the Isthmian Canal was already doomed as too small for the requirements of the future. He, therefore, thought everyone would welcome the idea which the author had enunciated, that they need not be content with what one might call a canal but look forward to what had been better described as the Straits of Panama. Another thing which struck him was that the recent sad experiences which had taken place at Jamaica, Valparaiso, and California seemed to indicate that a great work of international importance in such a locality as Central America and the Isthmus of Panama ought, if possible, to be so designed that what were called works of art should be altogether avoided. A system of a lock canal in a volcanic neighbourhood subject to earthquakes could not be looked forward to with complacency; and when the enormous amount of money which was to be spent on the work was taken into consideration, it seemed to him as an outsider—because he was only an outsider in this particular matter—that anything in the nature of large masonry dams and locks closed with gates, which would be absolutely wrecked by comparatively small shocks of earthquake, should be avoided in such a magnificent undertaking.

Mr. E. W. MOIR said he did not know much about the Panama Canal, but he could fully endorse the author's statements with regard to the advantages of dredging as against excavation in the open, and also the increased power of modern dredging plants compared with what was possible within comparatively recent times. His own firm of S. Pearson and Son had extensive dealings in dredging plant, and only in the previous week placed with Messrs. Lobnitz an order for a dredger which was guaranteed to put out over a thousand yards an hour from a depth of 45 feet in soft ground. The buckets were of a cube capacity of one metre, and guaranteed to travel at the rate of 18 buckets per minute. He had often had conversations with Mr. Lobnitz about his rock-breaker. Mr. Lobnitz's father began the work of building dredging plants on the Clyde, and the son was ably carrying on the work in his father's footsteps, and told him that quite recently he had seen figures of the Manchester Ship Canal costs which indicated that sub-aqueous rock dredging was being carried out at a smaller figure than it was possible to take out the same rock with ordinary boring and explosives on the surface. That evidence, therefore, conclusively confirmed what the author had said. He thought the reason the Americans had decided on the lock canal system was largely due to their desire to have the canal pushed through within the memory of the present generation. While the International Commission exclusively reported in favour of the sea-level canal, although of course on a much smaller section than that suggested by the author, they felt that it would take too great number of years to make. His firm was very interested in the Isthmus of Panama, and Sir Weetman Pearson was only on that very day opening the Tehuantepec Railway, and the connecting harbours. For the last eight years, Sir Weetman had been erecting a railway across the Isthmus of Tehuantepec, and building two ports, one at Coatzacoalcos, on the Gulf of Mexico, and the other at Salina Cruz on the Pacific, which would give from the present day a communication of much less distance than anything now existing, or that would exist even after the Panama Canal was completed. The distance between New York and San Francisco was 1,000 miles less than it would be between the same places by the Panama Canal when completed, although the railway was only 192 miles long. His firm were in partnership with the Mexican Government in the control and working of the railway, and they expected great things for international trade. One line of steamships, instead of going round the many thousands of miles *viâ* Cape Horn, had arranged for its freight to pass over the Isthmus; and, due to the fact that Americans were wise enough to insist that all coast trade should be carried in American bottoms by American seamen, a very large sum of money had been invested in ships under the American flag to carry the freight from New York to San Francisco.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Bunau-Varilla for his interesting and instructive paper.

Mr. BUNAU-VARILLA, in reply, remarked that reference had been made to the enormous strides which had taken place in water-borne excavation compared to earth-borne excavation. Outside of those due to the enormous increase in the size and power of the dredges, there is another which will play an important part in Panama—the use of electricity. On board a dredge, the actual cost of the dredging lay not so much in the work done as in the time lost and the occurrence of accidents. As dredges are excavating material they cannot see, they are exposed to hidden obstacles, and abnormal resistance is from time to time imposed upon the machinery. But when the motive power is electric, as soon as the resistance comes to a fixed limit the current stopped and the accident avoided. That is a very important factor in the cost of the work. In 1895, while he was constructing a railway in the west of Spain, he took advantage of having to remove a large quantity of ballast from the river Esla to make experiments with regard to the adaptation of electricity to dredging, and they entirely fulfilled his

expectations. The employment of electricity on board a dredge led to a considerable economy in time by the prevention of small accidents. He could not conclude without expressing his deep gratitude for the hospitality which had been shown him by the Society of Arts. The hall of the Society was a most suitable place in which to state his opinions, because it was neutral and friendly, and situated in a country which was closely linked with his own by ties of the deepest friendship.

THE RAILWAY AND TRAMWAY SYSTEMS OF JAPAN.

The first Government railway built in Japan was that between Tokyo and Yokohama—eighteen miles—which was opened in 1872. From that time the Government made every effort to construct more lines, until, by the financial year 1882-3, 150 miles had been completed. The railway was at the time generally looked upon as a Government undertaking, and no attempt was made among the general public to engage in railway enterprise. In 1883, however, a private company was for the first time formed for the construction of railways, and thereafter railway enterprise made gradual progress among the people. In 1887 the Private Railways Regulations were issued, and both Government and private railways increased and grew rapidly in prosperity. At the present time private lines have, in mileage, left the Government lines far behind. In March, 1900, the Private Railways Law and the Railway Traffic Law were promulgated, thereby completing the legislation, private and public, in respect of railways. In March, 1905, the Railway Mortgage Law was issued with the approval of the Imperial Diet, and opened the way for the circulation of capital, for this law enables a private railway company to form a railway foundation with the whole or part of its railway lines, land for railway use, buildings, machinery and appliances for railway use or appertaining to the railway, and rolling-stock and appliances appertaining thereto, and make such foundation the object of a mortgage right. The principle of railway nationalisation first took effect in Japan when railways were projected between Shimbashi and Yokohama, and Kyoto and Kobe, and in 1892 was established the Railway Construction Law, which mapped out the important lines throughout the country, and indicated the general plan of working such lines by means of railway loans. Before, however, this law was passed, it had been decided that it would, for the purpose of effecting a speedy construction of railways, be best to leave such construction to private enterprise, and in 1887 the Private Railways Regulations were issued. Since then Government and private lines have extended side by side. At the present time, in view of the necessity for a definite post-bellum programme and for the increase of national wealth and development of national resources, it has, according to a recent report of the Japanese Ministry of Finance, become of the utmost importance to introduce effective means of internal transportation and communication. In addition to the Government lines, there are more than thirty private railways, and even the principal trunk lines running from Hokkaido to Kyushu are under the control, some of the Government and others of various private companies, so that the traffic on them lacks order and uniformity. For these reasons the Japanese Government decided upon the State ownership of all railways that are used for general traffic, leaving out those of merely local importance, and proposed to purchase the lines belonging to thirty-two private companies within a period extending from 1906 to 1911, and the Seoul-Fusan Railway in 1906. Accordingly the Railway Nationalisation Bill and the Seoul-Fusan Railway Purchase Bill which embodied these plans, were presented to the Imperial Diet, and were duly passed, with an amendment made in the House of Peers, by which the number of companies to be bought out was reduced to seventeen, and the period of purchase extended. The lines to be purchased under the Railway Nationalisation Law are those belonging to seventeen companies, namely, the Nippon, Sanyo, Kobu, Kwansai, Kyoto, Hankaku, Hokuyetsu, Nishinari, Nanao, Ganyetsu, Kyushu, Hokkaido-Tanko, Hokkaido, Sangu, Sobu, Boso, and Tokushima, all of which are main trunk lines used for general traffic. Their aggregate length is 2,812 miles, and cost of construction about £23,463,000. The Government is to purchase the above-mentioned railways within a period of ten years from 1906 to 1915. The purchase price is to be calculated in the following manner:—(*a*) An amount equal to twenty times the sum obtained by multiplying the cost of construction at the date of purchase by the average ratio of the profit to the cost of construction during the six business terms of the company from the second half year of 1902 to the first half year of 1905; (*b*) the amount of the actual cost of stored articles converted according to current prices thereof into public loan bonds at face value, except in the case of articles which have been purchased with borrowed money. The first electric tramway built in Japan was a line eight miles in length opened in Kyoto in 1895, when a national industrial exhibition was held in that city. Since then, other cities of importance have in succession constructed electric tramways as convenient means of communication for short distances, so that there are now eighteen electric tramway companies, with an aggregate capital of £3,891,000, whose lines already opened total 130 miles, with 82 miles in addition under construction. Most of the companies, however, are still in the initiatory stage and do not yet make a very profitable business of the undertaking. That the profits will be large, however, is clearly shown by the fact that the electric tramways of Tokyo already pay annual dividends of not less than 10 per cent.

HOME INDUSTRIES.

The Growth of British Trade.—Naturally there has been much congratulation over the Board of Trade figures which show that the export and import trade of the United Kingdom in 1906 amounted to £1,069,000,000, exclusive of bullion and specie, the increase in the export trade, as compared with that of 1905, being 13·6 per cent., and in imports of 7·4 per cent., but there cannot be full appreciation of these figures without showing among other things—(1) the effect of the rise in prices, (2) the condition of home trade, (3) the trade expansion of other countries for the year. With regard to values, Mr. Sauerbeck has published a memorandum in which he arrives at the conclusion that the rise in wholesale prices in 1906 in the United Kingdom was 6·8 per cent. According to the Board of Trade figures the increase of imports into the United Kingdom in 1906 was 7·4 per cent., of which 5·3 per cent. represent increase in values, so that there was only an increase of 2·1 per cent. in quantities. Again, with exports, the increase of 13·6 per cent. given by the Board of Trade falls to 8·3 per cent. if the increase in values is deducted, and the increase of 10 per cent. in the values of total trade becomes a trifle under 5 per cent. in quantities. Even the smaller figures show not unsatisfactory expansion of trade. Of course, the condition of home trade is a most important factor in appraising the general condition of trade. There may be growth of exports due to stagnation of home markets, and in that case, or if the growth is accompanied by a growth of imports in the manufacture of which there is a larger percentage of labour than in the manufacture of exports, it would not be a proof of national prosperity. Unfortunately at present, the data are wanting to enable a sound conclusion to be arrived at as to the condition of home trade, but it is to be noted that imported manufactures increased 1·7 per cent. in 1906, as compared with 1905, while exported manufactures increased 7·9 per cent., the growth in the exports of manufactures being practically equal in ratio to the growth of exports in all classes combined. Turning to our chief commercial rivals—the United States, Germany, and France—there are no available estimates of the change in price in these countries, but the increase in the import and export trade of the United States was 11 per cent., of Germany 12½ per cent., and of France 7 per cent., as compared with the 10 per cent. of the United Kingdom. Taking exports only, the increases were—the United States 12·2 per cent., Germany 9·7 per cent., France 5·3 per cent., as compared with the 13·6 per cent. of the United Kingdom; and turning to imports, the United States show an increase of 10 per cent., Germany of 14·9 per cent., and France of 9·1 per cent., as compared with the 7·4 per cent. of the United Kingdom. It may be assumed that the effect of the rise in values has been at least as great in these three foreign countries as in Great Britain, and so much is said about the expansion of German trade, that many will note with surprise that whilst German imports show a much larger increase than those of the United Kingdom, an increase which may be taken to be due in considerable measure to the growth of food imports, German exports increased only 9·7 per cent. as against the 13·6 per cent. of the United Kingdom. Looked at from any point of view the trade figures would seem to prove that in 1906 the United Kingdom more than held her own in the trade of the world. But it will be well to bear in mind that the upward trend of trade cannot go on indefinitely A movement in the opposite direction must come, and whilst present indications suggest that probably it will not come this year, the outlook in the United States suggests misgivings.

Southampton and Liverpool.—The migration of the steamships conducting the mail service of the White Star Line from Liverpool to Southampton is a noteworthy event in the North Atlantic shipping trade. It is contended that the explanation of the change is, any way in part, the desire to meet the growing demand of travellers that facilities shall be provided to enable them to embark and disembark at either a Continental or a British port. The White Star vessels will sail from Southampton on Wednesdays, and will then call at Cherbourg and Queenstown. On the return journey they will call at Plymouth then Cherbourg, terminating their journey at Southampton. The change does not mean that the connection of the White Star Line with Liverpool has terminated. Not only will the weekly passenger service be maintained by the *Baltic*, *Celtic*, *Cedric*, and *Arabic*, but the Liverpool and Boston passenger service, the Australian service, and the regular weekly services of live-stock and cargo steamers will be maintained as heretofore. But the loss to Liverpool from the transference of the *Oceanic*, *Majestic*, *Teutonic*, and *Adriatic*, to Southampton will be considerable, and it comes just as the Mersey Docks and Harbour Board have made immense efforts to adapt the port of Liverpool to the most modern requirements. It is understood that it is not the present intention of the Cunard Company to go to Southampton, and if they go to a Channel port it may be to another than Southampton, which will have quite enough to do for the present in providing the accommodation required by the monster steamers of the White Star Line. Probably the Cunard Line will prefer to remain at Liverpool, where they have secured practically the whole of the large increase which took place last year in the passenger traffic between Liverpool and New York. But a good deal may depend upon what becomes of the proposals with regard to the basis upon which dock tonnage rates are levied, which are contained in the Bill to be presented to Parliament by the Mersey Dock and Harbour Board. At present these dues are levied on the net tonnage. The Bill proposes that they shall be levied on a proportion of the gross tonnage. To this the Cunard Company is strongly

opposed, believing it would seriously handicap the large mail steamers in which there is a marked disparity between the gross and the net tonnage. But it is quite possible that Parliament will reject the proposals of the Board, seeing that a Committee of the House of Commons has reported against them upon the ground that they would only affect a small percentage of tonnage, and that consequently it is not worth while altering the existing arrangements, more especially as such alterations might lead to international complications.

The Cotton Industry in 1906.—The Board of Trade returns show that 1906 was a very prosperous year for the cotton industry, and the *Economist* summarises the facts and figures in a very interesting article. The cotton piece-good shipments of the year show an increase in yardage, as compared with 1905, as from 6,196,783,900 to 6,261,295,000. Last year's shipments of bleached and grey cloths were less than in 1905, the increase being in printed and dyed goods. The largest increased takings were by Turkey, 102,744,000 yards, the Argentine Republic being a far behind second with an increase of 33,804,000 yards. Throughout the year makers were busy at a fair profit which, however, was less in the latter half of the year, owing to the abnormal rise in American yarns. Users of Cop twist and weft had to pay much higher rates, and could not get a corresponding advance in cloth. The year shows substantial profits on capital employed, but as in 1905 the gain was larger in weaving than spinning. Home made goods were active in nearly all descriptions, and the distributing houses were busy throughout the year. Many new looms were put down in 1906, and more projected. The estimate for the last two years is 80,000. As the new weaving sheds got to work there sprung up a good demand, and by the middle of the year there was almost a scarcity of yarn. Although the production was larger owing to the starting of new factories, it was fully absorbed all through the last six months of the year. Shipments of yarn were larger, 207,373,100 lbs. as against 205,100,500 in 1905, the Netherlands showing the largest increase in taking 2,310,000 lbs., Japan coming close with 2,244,000, and Germany third with 1,501,000 lbs. The price of raw American cotton fluctuated considerably, being at its lowest point in August, when 5·29d. was the rate, and highest in October at 6·45d. per lb., the average price in Liverpool being 5·95d. per lb. as compared with 5·09d. in 1905. The crop of the year ended August amounted to 11,319,000 bales, the best expert opinion putting the crop of the current year at 13,000,000 bales. During the last eighteen months 18 new spinning mills, with 1,627,355 spindles, using Egyptian cotton, have got to work, seven new mills with 595,000 spindles have partly commenced, and 14 new mills with 1,440,000 spindles are being erected. Of new mills spinning American cotton, fifteen, with 1,265,000 spindles, have during the same period been got fully to work; eleven with 1,002,000 spindles have got partly to work, thirty-one with 2,561,000 spindles are in course of erection, and three with 300,000 spindles are projected. Taking the net profit and loss of the spinning trade since 1884 a larger profit was made in 1906 than in any year of twenty-three except 1905. As to the outlook for the present year it remains to be seen whether the great extensions in the spinning and weaving departments will be met by the demand, but on the whole probabilities point to another prosperous year, if only the present amicable relations between masters and men continue.

Electricity in Cotton Mills.—Mention has been made from time to time in these Notes of experiments in the electric driving of cotton mills. The first electric-driven mill in the United Kingdom was started in Scotland three years ago, but they have been known in South Carolina for the last fifteen years. The Lancashire mill owners who have adopted the electric drive say they are satisfied with it. The systems adopted are either the arc unit or the group system, but the two may be to some extent combined by forming small groups. There is an absence of speed variation in cotton mill machinery which would seem to make such plants specially adapted for electric driving. As a writer in the *Manchester Guardian* has pointed out the actual horse-power required to work each machine is not generally known with sufficient exactitude, so that the electrical engineer is obliged to make tests in order to properly apply the system to be adopted. If electric driving fulfils the expectations of its friends it will no doubt be installed in existing mills as this can easily be done without causing a stoppage of work. The experiments now being carried out to test the comparative value of electric driving systems will be watched with keen interest.

A New Insurance Departure.—The inclusion of domestic servants in the Workmen's Compensation Act means a great accession of business for some of the insurance companies, and will find work in canvassing for many new hands, among whom, it may be expected there will be a considerable portion of women. For the well-to-do, the burden of insurance will be infinitesimal. Already the rates vary considerably, but in no case that the present writer has seen are they large. Policies are offered to cover the mere legal liability of domestic servants at 3s. per servant, and others, which not only give complete protection against strict legal obligations, but will enable employers to carry out moral obligations they may feel towards those in their service, at 5s. per servant.

CORRESPONDENCE.

PATENT-LAW REFORM.

After reading the recent interesting paper and discussion on the above subject, it was the intention of the writer to contribute a word or two by way of

emphasising a suggestion made by one of the speakers from an inventor's standpoint, but what he intended to say has been so fully anticipated in the letter sent by Mr. Hardingham, that further remarks are scarcely necessary.

Those who have had long experience relating to inventions and patents, know that in order to get the merits of a good patent duly appreciated, several years are often consumed in the process.

The initial stage of the proceeding is often done without remuneration and sometimes at a loss. Generally speaking it is only at the fag end of the lifetime of the patent that a fair remuneration is realised by the inventor or patentee. Under these conditions the time limit of a good patent should not be a bit less than 18 years; this would give more encouragement to the inventive faculty.

The premium for renewing should be placed within the reach of most moderate means, say much about the same cost of securing a patent for the United States of America.

It is hoped that the promoters and drafters of the new Bill will not lose sight of the injustice with which the English inventor has to combat against, the prohibitive conditions and tariff which bar in a great measure an English inventor and patentee from selling his patented goods in a foreign country, while the foreigner can import and sell his patented articles in the United Kingdom free of rates, taxes, and other expenses. This should not be allowed to continue.

ISAAC SMITH (of Sydney Smith and Sons).

OBITUARY.

THOMAS SEBASTIAN DAVIS. — Mr. Sebastian Davis, who had been a member of the Society of Arts since 1882, died on the 30th December last, at the age of 78, having been born at Kennington, in 1828. He was a very early member of the Photographic Society, which he joined in 1857; was a very constant attendant at its meetings, and for many years served on its Council. He always took a great interest in photographic progress, and was himself—especially in earlier years—an ardent experimentalist. He was a Fellow of the Chemical Society, and an original member of the Society of Chemical Industry. By profession he was an analytical chemist. Mr. Davis was a frequent attendant at the Society's meetings, and occasionally took part in its discussions.

GENERAL NOTES.

THE TRADE OF MOROCCO.—The Anglo-French Agreement has been followed by great increase in French trade with Morocco, mainly at the expense of the United Kingdom. There has been a large influx of Frenchmen into Morocco, the number of French residents, exclusive of Algerians, being now probably treble what it was three years ago. Important French banks have been established at Tangier, with branches at the other ports, and French firms have established houses of business at the towns of the interior as well as at the ports. The French Government has also granted subsidies to steamship companies to run mail steamers to Tangier at regular dates, thus increasing French shipping and giving greater facilities for trade with France and Algeria. In his report on the trade of Morocco, just issued (Cd. 2682), Mr. Consul White gives tables which show that the percentage of exports to the United Kingdom from Morocco fell from $28\frac{3}{4}$ in 1904 to $24\frac{7}{8}$ in 1905, whilst those to France increased from $22\frac{7}{8}$ per cent. to 32 per cent, and the imports from the United Kingdom have in the same period fell from $50\frac{3}{8}$ per cent. to 36 per cent., whilst those from France increased from $31\frac{3}{8}$ per cent. to $43\frac{3}{4}$ per cent. The United Kingdom has pretty well maintained its position as to shipping, the decrease being only from $34\frac{7}{8}$ per cent. to $33\frac{5}{8}$ per cent., but France has increased her percentage from 21 per cent. to $29\frac{7}{8}$ per cent., mostly at the expense of Germany, Spain, and Italy.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

JANUARY 30.— "Apprenticeship." By JAMES PARSONS, M.A. SIR WILLIAM BOUSFIELD, M.A., LL.D. will preside.

FEBRUARY 6.—"The Principles and Practice of Insurance, and their modern Developments." By THOMAS EMLEY YOUNG, B.A, Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association.

FEBRUARY 13.—"Motor Omnibuses." By LORD MONTAGU OF BEAULIEU.

FEBRUARY 20.—"Cold Storage and Food Supply." By HAL WILLIAMS.

FEBRUARY 27.—

MARCH 6.—"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 14.—"The Practical Side of Famine in India." By SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces.

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

JANUARY 29.—"Artistic Treatment of the Exterior of the Pianoforte." By WILLIAM DALE, F.S.A. T. G. JACKSON, R.A., will preside.

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. This paper has been unavoidably postponed from February 19th.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

LECTURE I.—JANUARY 28.—*Alluvial Gold Mining.*—Small scale methods and manual appliances—Hydraulic sluicing — Gold dredges; chief types; ground to which suitable; costs—The deep leads of Australia; their nature; distribution; methods of discovery and mining.

LECTURE II.—FEBRUARY 4.—*Lode Mining.*—The term "reef" used both for ore and "country" rock—The chief types of gold-bearing lodes—The importance of ore genesis in reference to mine development—The chief gold fields of the world and their structures—The Rand and its banket.

LECTURE III.—FEBRUARY 11.—*Gold Production.*—The crushing of the ore; the stamp mill—The extraction of gold by amalgamation; smelting; chlorination and cyanidation—Reforms in consequence of the tube mill and the filter press—Tube mill *versus* pan—Proposed abolition of the stamp battery—The depth of ores; surface and secondary enrichment—Mining costs and gold mining organization.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. John Walter Gregory, "Gold Mining and Gold Production." (Lecture I.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr R. Orlebar, "The Report of the Agricultural Committee on Tariff Commission."

East India Association, Caxton-hall, Westminster S.W., 4 p.m. Mr. Nasarvanji M. Cooper, "Prospects of Indian Labour in British and Foreign Field."

Surveyors, 12, Great George-street, S.W., 8 p.m. Dr. Henry Woodward, "The Uses of a Geological Collection."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Major C. D. Bruce, "A Journey through Central Asia to Northern China."

Actuaries, Staples-inn-hall, Holborn, 5 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Professor Sir William Ramsay, "The Transmutation of Elements."

TUESDAY, JAN. 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. William Dale, F.S.A., "Artistic Treatment of the Exterior of the Pianoforte."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. C. Seward, "Survivals in the Past from the Plant World." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. James Tayler Milton's paper, "Internal-Combustion Engines for Marine Purposes."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W. 4½ p.m. Mr. Edward H. Miller, "Rhodesia and its Resources."

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W. 8 p.m. 1. Discussion on "Osmotic Pressure." 2. The Earl of Berkeley will exhibit and describe his Apparatus for the Direct Measurement of Osmotic Pressure. 3. Mr. W. C. Dampier Whetham, "Indirect Methods of Measuring Osmotic Pressure." 4. Dr. T. Martin Lowry, "Osmotic Pressure from the standpoint of the Kinetic Theory."

WEDNESDAY, JAN. 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. James Parsons, "Apprenticeship."

United Service Institution, Whitehall, S.W., 3 p.m. Lieut.-Col. F. S. Davy, "The Blot on Recruit Training."

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, JAN. 31...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. J. Tabor, "Hints on Collecting Old China."

Royal Institution, Albemarle-street, W., 3 p.m. Major Percy Macmahon, "Standards of Weights and Measures." (Lecture I.)

FRIDAY, FEB. 1...Royal Institution, Albemarle-street, W., 9 p.m. Sir Almroth E. Wright, "The Methods of Combatting the Bacteria of Disease in the Interior of the Organism."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "The Palace of Minos."

Geologists' Association, University College, W.C., 7½ p.m. Annual Meeting.

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, FEB. 2...Royal Institution, Albemarle-street, W., 3 p.m. Rev. William Barry, "Papal Deposing Power." (Lecture I.)

Journal of the Society of Arts.

No. 2,828. VOL. LV.

FRIDAY, FEBRUARY 1, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 4, 8 p.m. (Cantor Lecture.) PROFESSOR JOHN WALTER GREGORY, D.Sc., F.R.S., "Gold Mining and Gold Production." (Lecture II.)

WEDNESDAY, FEBRUARY 6, 8 p.m. (Ordinary Meeting.) THOMAS EMLEY YOUNG, "The Principles and Practice of Assurance and their Modern Developments."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, January 28, Professor JOHN WALTER GREGORY, D.Sc., F.R.S., delivered the first lecture of his course on "Gold Mining and Gold Production," the particular subject being alluvial gold mining. The lecturer described the various manual appliances in use—hydraulic sluicing and the chief types of dredges. Also the nature and distribution of the deep leads of Australia. The methods of discovery and mining were described.

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday, January 29, 1907; T. G. JACKSON, R.A., in the chair. The paper read was "The Artistic Treatment of the Exterior of the Pianoforte," by WILLIAM DALE, F.S.A.

The paper and report of the discussion will be published in a future number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, January 15; COLONEL SIR FREDERICK D. LUGARD, K.C.M.G., C.B., in the chair.

The CHAIRMAN, in introducing the author of the paper, said that Mr. Wilson had spent some eighteen or nineteen years in Uganda, so that there were very few men who had more first-hand knowledge of the country. Mr. Wilson was a very old friend and comrade, having been his chief lieutenant in East Africa during 1889 and 1890. He was very sorry that when he went to Uganda, Mr. Wilson could not accompany him, but he followed shortly afterwards.

The paper read was—

THE PROGRESS OF THE UGANDA PROTECTORATE.

By GEORGE WILSON, C.B.,
Deputy Commissioner, Uganda Protectorate.

INTRODUCTION.

I submit this paper upon the subject of "The Progress of the Uganda Protectorate" with a view to placing before you pictures of two periods in the history of the countries which have ultimately become constituent parts of that Protectorate. The first period will date from the revelation of the mystery which obscured the existence of those regions, a revelation made under the auspices of the Royal Geographical Society by Captain Speke's memorable discoveries in 1860, to that of the historic introduction of authoritative British influence by Captain Lugard under the flag of the Imperial British East Africa Chartered Company in 1890; an era which may be described as the base upon which we have

erected our structure of moral and economic progress. The second period is simply that of the present.

In these two pictures it is my intention to convey to you a clear impression of the beneficent influence which sixteen years of civilising work under British protective dominance has had upon barbarous countries, concurrently with a proper regard being given to Imperial economic considerations. Of these sixteen years four passed under the authority of the British Chartered Company, whose aspirations were patriotic and grandly imperial, but to whose field and scope of exploitation there must of necessity, and from obvious causes, have been some limitations. The remaining twelve years have had the more complete advantage of the sympathetic control of the British Government.

Geographical Situation.

It may lead to an easier grasp of the subject if I at once give a brief description of the geographical position and composition of the Uganda Protectorate in its present complete form. It mostly lies between the 5th degree north latitude and the 1st degree south, with a mean length of 300 miles, and between the 30th and 35th degrees east longitude, averaging in breadth under 300 miles. This area of between 80,000 and 90,000 square miles probably contains about 3,000,000 people, of diverse tribal characters.

Great Lakes.

Situated on the south-east corner of this territorial block is the greatest of the African lakes, the Victoria Nyanza, the existence of which immense sheet of water was a subject of old traditional belief left to be confirmed by Speke's discovery in 1860. Its greatest length is 250 miles and breadth 200 miles, and it is 24,000 square miles in extent. This is a magnificent sheet of water, and is placed next only to Lake Superior in the list of the world's largest fresh water lakes. It is studded with beautiful islands particularly on the west, where there is also an outlet over the Ripon Falls into the Victoria Nile, to which great river it gives birth. At these falls a peculiar reef barrier completely impedes navigation; Sir William Garstin indicates, in his splendid schemes for the regulation of the Nile flow, that it may lend itself to a future barrage scheme for Egyptian irrigation purposes. Though the Falls themselves can be described more as beautiful than grand, having only an actual drop of from seventeen to twenty feet along a distance of about three-quarters of a mile from bank to bank, they offer attractive opportunities for the economic utilisation of hydraulic force. Then running along the extreme western frontier of the Protectorate we have the Albert Edward and Albert Lakes. The former is about 43 miles long by 31 miles wide, and 900 in extent. Then Albert Lake is under 100 miles long by from 18 to 27 miles wide, and covers an area of 1,960 miles. Apart from this group, there is, isolated on the extreme north-eastern boundary of the Protectorate, the Lake Rudolf, 190 miles in length by 20 in breadth, and covering an area of 4,000 miles.

The relative heights of these lakes above sea level is, according to Captain Behren's recent paper—Victoria Nyanza, 3,720 feet; Albert Edward, 3,004 feet; Albert, 1,937 feet; Rudolf, 1,250 feet.

The differences in levels of the Nile series of lakes are accomplished as follows:—From the Victoria Nyanza to the Albert, 716 feet in 250 miles of river way, and from the Albert Edward to the Albert, 1,067 feet in 160 miles; in each case the grade, slight as it is, is affected by instances of falls and rapids.

Some discussion is at times given to the conjecture that these lakes are gradually diminishing. My own observations of the Victoria Nyanza during some years induce me to believe that the lakes are fully susceptible to rainfall. The phenomenal rains of last year have increased the volume of the Great Lake to within an ace of that of the highest visible water-mark, and I think we need have little anxiety that there will be any diminution likely to affect practical schemes within our range of interests.

Ruwenzori Range.

Another physical feature of very special character is the Ruwenzori range of mountains lying between the Albert Edward and the Albert Lakes, and said, after much interesting controversy, to be about 17,000 feet high.

Composition of Protectorate.

I will now enter upon a description of the countries comprising the Protectorate at the present day. For administrative purposes they are classified into five provinces. Of these there are under settled native organisations of government: the Uganda Kingdom, lying on the north-eastern corner of the Victoria Nyanza; the Western Province, con-

taining the smaller kingdoms of Unyoro, Toro, and Ankole, filling the South Western corner and part of the Western Frontier, and abutting on the Albert Edward and Albert Lakes. Under more direct Government control, due to an absence of local cohesive government systems, we have:—The Central Province, comprising Usoga and Mount Elgon and the territory lying between it and the Victorian Nile, in its Western course into the Albert Lake, and the 5th degree north latitude; and, lastly, the Rudolf Province, which holds the countries between Lake Rudolf and the Nile Province. This province is not as yet effectively administered, and will scarcely be more than alluded to in the course of this reading.

The Uganda Protectorate is about 700 miles from the sea coast. Between the two is the East African Protectorate, one quite distinct from that of Uganda, with which we are now dealing. The situation of Uganda was so remote that even when Speke reached the country only a few Arab traders had preceded him, and it is believed that no foreigners had entered the country from the more civilised parts between the time of the arrival of a superior caste some four or five centuries earlier, and the nineteenth century.

Early History.

Having thus located in our minds the position of the countries to be brought under consideration, I will take up the task of depicting the early conditions upon which the tale of progress is to be founded. I have said that up to 1860 the whole of these regions were shrouded in mystery, and that it remained for Speke to lift the veil in 1860 and 1862. He was followed by Stanley in 1875, after which we have a splendid array of names of explorers to aid the compilation of the story of Uganda and the surrounding countries.

The earliest travellers were all greatly impresssed by the barbaric power manifested in the Uganda and Unyoro kingdoms, and particularly with the remarkable organisation which characterised the system of government in Uganda alone of all the Central African countries. They found there full confirmation of the current tradition that some centuries earlier a northern element had entered the country and at once won ascendancy, substituting administerial systems marking a high order of intelligence for the aboriginal conditions common to such countries. A more intellectual stamp of feature distinguished the descendants of this race, being most conspicuous perhaps in the members of the reigning family.

Being anxious to convey accurate ideas, I will solicit your patient hearing of perhaps copious extracts from relations of actual experiences, certain that such first-hand accounts must be more telling than any condensed paraphrasing of mine. In reference to the Uganda "King" Mtesa and his chiefs, and the assertion of the kingly authority, Speke writes:—

"No one dare stand before the king whilst he is either standing still or sitting down, but must approach him with downcast eyes and bended knees, and kneel or sit when arrived. To touch throne or clothes, even by accident, or to look upon his women, is certain death. . . . . . It is the duty of all officers, generally speaking, to attend at Court as frequently as possible. Should they fail, they forfeit their lands, wives, and all belongings. Tidiness in dress is imperatively necessary, and for any neglect in this rule the head may be forfeited."

In recounting his preparations for his reception "at Court" Speke goes on to say:—

"To-day the king sent his pages to announce his intention of holding a levee in my honour. I prepared for my first presentation at Court attired in my best, though in it I cut a poor figure in comparison with the display of the dressy Waganda. They wore neat barkcloths, resembling the best corduroy cloth, crisp and well set, as if stiffened with starch, and over that, as upper cloaks, a patchwork of small antelope skins, which I observed were sewn together as well as any English glovers could have pieced them."

He goes on to describe the dress of the King at this reception in this fashion:—

"Everything was light, neat and elegant in its way, not a fault could be found with the taste of his getting up."

Some twelve or thirteen years later Stanley makes the following allusion to Mtesa:—

"The chief reason for admiration lay, probably, in the surprise with which I viewed the man whom Speke had beheld as a boy—and who was described by him through about two hundred pages of his book as a vain, peevish, headstrong youth and a murderous despot, sedate and composed in manner, intelligent in his questions and remarks beyond anything I expected to meet in Africa. That I should see him so well dressed, the centre of a court equally well dressed and intelligent, that he should have obtained supremacy over a great region into which moneyed strangers and soldiers from Cairo and Zanzibar flocked for the sake of its supreme head, that his subjects should speak of him with respect, and his guests, so far as I could gather, honour him, were minor causes, which I venture to consider were sufficient to win my favourable judgment."

In other writings we find allusions to "His Majesty" and the "Earls," and phraseology generally which seems to us, in our superior and more comfortable knowledge, incongruous when applied to such a barbaric power. It certainly requires an effort of thought to hark back to the circumstances and conditions which produced the attitude of mind marking the writings of our early explorers in their references to Uganda. We must remember the vicissitudes they encountered in accomplishing their discoveries, the absence of pomp or any of the paraphernalia of government authority, and the great weight of the impressions which men travelling under such disabilities must have felt in emerging from the meaner conditions of countries of disintegrated control upon the comparatively splendid isolated organisation of Uganda. We have only to read Sir Samuel Baker's accounts of how he was made to feel the power of even such a lesser potentate as Kaba Rega to grasp in some degree a sense of the expressions which pervaded the writings of those days. After all, the impressions of which I speak were acquired by Englishmen, whose names were surely a guarantee for a sensible statement of visible facts, and so we should interpret their expressions. If there is any feeling of incongruity of expression, as viewed from present-day standpoints, instead of being critical of them let us rather reflect how is it that with all our advanced facilities for civilising work we have not carried on the native power with a worthiness for the same characterisation since the introduction of foreign influences. For my own part I see no need to be despondent, for it is not long since that power was exercised in much of its old time strength, when hundreds of European lives depended much upon the effectiveness of that power, a historical and significant fact which at times escapes the memory in our anxiety to reform native countries out of all recognition of their natural selves. This has, perhaps, been somewhat of a digression, but it fills part of my purpose in emphasising the fact that it has been a not altogether ignoble base upon which the stages of progress have been built.

But the display of barbaric power had the usual concomitants of unbridled gratification of the passions and caprice. Even hundreds of lives were immolated on the impulse of a moment, on a known occasion merely, as the King said, "to bring these people to a fitting sense of due subjection to authority." Nevertheless, bad as conditions were, and sad as is the picture which has been drawn of those terrible times, a trace of justice could usually be discerned in general procedure which had hitherto been greatly deficient in the reign of Mtesa's predecessor, and was altogether lacking in that of his successor.

A few words will bring history up to the date of the introduction of British authority. Mtesa had died after having done his best to elevate the country and himself to greatness. He had much changed the character of the circumstances of state; throne, gold embroidery, parades of firearms, and evidences of extended foreign trade were witness to his disposition to move out of the purely native groove. Moreover, his receptiveness of modern ideas had improved his character, and he left his country dominant in those regions. His place had been given to Mwanga, a man in whose nature power developed the most despicable meannesses, and in his hands began the country's decline. Colonel Lugard has likened the young king to Rehoboam, and remarked that, "whereas in the days of Mtesa there had usually been some show of accusation and condemnation, or at least of cause, for any arbitrary seizure and execution, there was now absolutely no security for life." Disputes and conflicts arose among aspirants for the throne with alternate repulses and successes. The good which might have emanated from an introduction of missionary influence at the earnest appeal of Stanley, was greatly modified by the creation of religious sectarian rivalries, and we have a long story of Protestant, Catholic, and Mohammedan conflicts which supplemented the King's incapacity in practically destroying the whole conditions of material prosperity in Uganda. But there were marvellous developments in the character of the people which seemed to be passing through a cleansing fire. Colonel Lugard, in reference to that time, says:—"Christian converts were burnt after mutilation and torture in great numbers, but they showed extraordinary heroism, and in many cases openly declared their faith and refused to escape, while others came forward to be baptised in spite of the fate which awaited them." It may be said in fact that the period of adversity which the country passed through, and the sustaining example and teaching of the missionaries evolved a much broadened and generally improved disposition, especially among the chiefs, and so by influence among many of the people; and this should be taken

as a sterling compensating advantage to be weighed against the depressing misfortunes which had fallen upon Uganda. But I doubt if it is too much to say that in this period between Mtesa's death and 1902, the country by strife, destitution, and emigration, lost a quarter of its population.

British Authority Introduced.

It was during the period of political chaos that Sir Frederick (then Captain Lugard) appeared upon the scene, and under the flag of the Imperial British East African Company laid the foundation of order with such splendid courage and ability, and with such sympathetic magnetism, that his name will ever be identified with the era of inauguration of civilised order and progress in Uganda. His name is a talisman wherever he has been, and I could wish to have, or to give to those countries, no greater satisfaction than in telling them I have again met him and received for them messages of kind remembrance.

Unyoro.

It has been impossible to refrain from giving almost exclusive attention to Uganda in these pages, so far did the attractions and interests of that country transcend those of any of its neighbours. Unyoro alone could claim some rivalling interest in the power it gained from its united subjection to one ruler. Is it not a historical truth that among African races such a ruling force is essential for their government, and that once that force which holds the masses together is wrecked and the people thrown upon their own resources for government, the decline of that race begins?

Notwithstanding this advantage, Unyoro itself had also, though in a somewhat different way to that of Uganda, undergone a partial decay. It yet included, as of old, the country known as Toro—since become a separate kingdom—and a large block of territory to the south, which lately was diverted to Uganda in warfare. It also possessed an ascendancy influential over much of the Nile and Central Provinces, and over part of the country to the west of the Albert Lake. Nevertheless, Kabarega, the king, was a savage, nothing more, and instead of ruling with the aid of an organised cohesive government, he maintained his dominance by a process of playing tribes off one against the other, a procédure already beginning to pave the way for the disruption which followed his later reverses. Like the rulers of Uganda, he was merciless in the assertion of his power, though not perhaps to quite so bloodguilty an extent as the more civilised king of Uganda, and hundreds of human lives were sacrificed merely at the promptings of capricious whims.

Ankole, Usoga, &c.

Very few words will be sufficient for allusions to the remaining countries. Ankole was a separate kingdom, liable to raids from Uganda, to which power it had from time to time been brought under subjection. This is the home of the Bahima, or Ba-huma, a much overrated race so far as they have proved themselves in that country. Usoga was under subjection to Uganda, occasionally rebelling but always suffering defeat with terrible slaughter. With regard to the more northern territories, those about Mount Elgon and in the vicinity of Lake Rudolf, little was known, and the countries of the Nile Province were part of the Egyptian-Soudan, which had been sadly harried and impoverished by the Dervishes.

Introducing Present Progress.

This completes my description of the base upon which civilising forces have built their progress. It will be seen that a powerful native kingdom had in the hands of an incapable king been allowed by factional troubles to become altogether disorganised, and that the first steps had been taken for the restoration of order by means of British influence and authority. I will now endeavour to convey to you an impression of the success which has been attained by those means. I do not propose on this occasion to follow all the stages of the gradual progression which has marked the building up of the Protectorate, interesting though they were, but to launch at once into an account of present day conditions.

Accessibility.

In doing this, the subject which I find brought most prominently to general notice is that of the enhanced accessibility of the Protectorate. To appreciate completely the advantage so gained it is essential that you should have in mind the foretime circumstances of travel. After landing at Mombasa, on the East African sea coast, amid surroundings crudely Oriental, it would be possible, after a month or so of infinite patience, to organise a caravan composed chiefly of slaves, who would be allowed to engage by their Arab masters on condition

that they were to have half share in the pay to be earned. If fortunate in securing capable supervision the caravan might be taken on fairly intact; frequently the only material available as porters would be bad, and desertions would dislocate arrangements. When *en route* there would be constant anxieties—water failing at the end of a long march where it could reasonably have been expected to exist; water having to be dug for; delays encountered in getting food supplies; plans to be devised for the carriage of food through even twenty days' marching through uninhabited country; precautions to be taken against savage tribes, principally nomadic; ever to be wary against misleading guides, against epidemics, whether of disease or temper among the men; and so cares would multiply until in the course of two or three months according to exigences, Uganda would be reached by the weary caravan. Think of the change brought about by the construction of the Uganda Railway and the establishment of steamers on the great lake! You now land at Mombasa to find it is so far Europeanised that you can obtain every requisite comfort, from accommodation in the hotels to the smallest necessaries in the outfitters. Trains run twice a week to the lake, so you can take your ticket, and in a railway journey of 584 miles pass, in less than 48 hours, through country attractive at times in its varied scenery, at others in the beautiful wild animals of its plains; and at more or less proper intervals, creature comforts can be satisfied at station restaurants. Then at the lake you meet the weekly steamers, each of 600 tons, nicely fitted even to electric lighting, and so in 18 hours, with stoppages, cross to Uganda over 170 miles of water begemmed with beautiful islands; a delightful experience altogether in fine weather, though in other weather, fortunately not common, the lake is quite capable of lashing itself into a fury which compels the vessels of earlier days to run to shelter. So that whereas in 1890, and, indeed, for some years later, the journey from Mombasa to Uganda occupied from two to three months, and carriage of goods, restricted to 60 lbs. loads, cost from £200 to £300 per ton, it can now be done under four days, and goods according to their class are carried in any required bulk at rates ranging from £3 to £15 per ton. Such exceptional merchandise as wines or spirits command higher rates.

The great steamer lines from Europe have also undergone their progress of improvement, and it is now usual to leave London *viâ* transcontinental railway routes to Marseilles or Genoa, there to meet the steamers and proceed to Mombasa, arriving there from seventeen to nineteen days from date of departure. Thus it is possible to reach Entebbe in twenty-one days from London, as our mails have actually done, or, in any case, in not more than twenty-five days.

The cost of transit of common produce from Entebbe to London under present circumstances is little over £5 per ton, and is steadily reducing itself; in fact, it is simply a matter of quantity, or even genuine prospects of quantity, upon which reduction depends. Concessions have been granted upon carriage of produce requiring special nursing, as well as upon agricultural implements, a term read very liberally by all the railway authorities.

Then we have excellent telegraphic communication and an admirably organised mail service, so that for a country so remote the Protectorate may be said to have as advanced means of accessibility as can reasonably be expected under the circumstances.

Entebbe.

On landing at Entebbe at a substantial pier, there will be seen good serviceable brick buildings, official, commercial, and residential, all now having passed the thatched-roof stage and entered that of painted iron and tiles. These for the most part are surrounded by well-tended gardens, and are situated on well-kept roads made beautiful by avenues of shady trees. Government House, the High Court, Hospital, Post Office, and other such buildings, mark the official character of the town, while a growing number of offices and shops and a busy activity in that quarter mark the steady advance of trade. In the early morning large numbers of natives can be seen falling into groups for the day's work, or for caravans moving into the interior. From 3,000 to 5,000 congregate daily in Entebbe for a labouring wage of 5s. to 6s. per month, and for porterage of, say from 6s. to 10s. There are also the Botanical Gardens, which to great beauty add great utility in the practical character given to its experiments. In the distance ecclesiastical buildings, ringing church bells and signs of much movement in that direction, denote, notwithstanding that Entebbe is not a great native centre, that degree of success in mission work which in these countries far exceeds that usually won in Central Africa. Then one is greatly impressed with the moderate temperature and by

the healthy appearance of the Europeans of both sexes; even by that of the very young children who in recent years have indicated by their presence a confidence in the increasing salubrity of the climate.

MENGO AND KAMPALA.

The same air of improving prosperity is spreading throughout the whole country. In Mengo, the Uganda native capital, a lead is given to all towns of especial native distinctiveness. There are seen conspicuous on hills, the king's residential and official buildings and three cathedrals, that of the Anglican Church being a stupendous structure, a fine example of the capabilities of natives under a strong supervision. Within view in the near distance is the Government Station, Kampala, with its well laid out official and commercial quarters. Throughout and dotted about among beautiful banana groves, are the large brick dwellings of the chiefs, rivalling those of the Europeans; while in the vicinity of the cathedrals are, a splendid hospital, schools of various grades, including industrial, and the residences of the members of the several missions. From the general centre diverge good roads to all parts of the Protectorate, and it is a cheering sight to view the continuous streams of natives passing along those roads, all bent upon peaceful avocations and with never a weapon among them. The stranger would be struck with the remarkable quiet of the Sunday, so strictly observed here—the streets and roads being quite empty during the hours of service, which thousands attend attired in their best.

GENERAL TOPOGRAPHY.

There is some variety in the general topography of the Protectorate, and much in the climate of its constituent parts. The main level of the country in the vicinity of the Lake Victoria is about 4,000 feet. After passing a narrow edge on the border of the lake undulating ground of luxuriant vegetation is met with. Then travelling over 50 or 60 miles of this there is another strip of comparatively bare country of 30 miles or so, leading on to yet higher country, generally of exceeding fertility. Travelling north after passing the Victoria Nile and away from the Nile banks, there are alternate fine pastoral and agricultural expanses with occasional lapses into sterile patches of more or less extent. The whole is well watered, in Uganda by slow running streams so checked by vegetable growth that huge swamps have formed: in other countries alternately by such swamps and by more or less beautiful rivers or streams.

AGRICULTURE.

Throughout many of these countries are seen huge and luxuriant banana plantations, an indisputable criterion of the richness of the soil, and in other localities are fine grain crops. Vast natural forests of useful timbers spread over portions of the country, sheltering valuable rubber vines, one forest, at least, including myriads of rubber trees. There are several others of which little is known. Then in the advanced spheres there are coffee and cotton of an almost indigenous character rapidly being supplanted by an extensive cultivation of better imported varieties. Trials of cultivation of imported coffee produce crops approaching one ton per acre per year, and the Mocha, Jamaica, Guatemala and Liberian varieties all thrive.

The field for cotton production seems to be unlimited, and although the industry on commercial lines is altogether new to the country, will reach several thousands of tons in the following year. So far all is produced by natives. Tests in Para rubber culture are quite successful, a fact of vital importance, as they promise to provide a substitute for great losses, caused by destruction in native collection, of indigenous rubber vines. The tests applied to many hundreds of trees prove a growth of seventeen feet in two and a-half years, and a general average growth of six feet per year. There has also been discovered a new rubber plant of great value, as well as the existence in great quantities of the *Funtumia elastica* trees of West Africa. Uganda prepared rubber has reached as high a price as 6s. per lb., and it is proposed to sustain, if practicable, the highest standard of its quality.

Sansivera and other fibres help to swell the exports, a recent discovery promising a variety valued at from £35 to £40 per ton. Indigenous chillies have had a great market for a time. Rice and lemon grass have proved successful. Tests in logwood, Brazil nuts, pimento, and cinnamon have made fully satisfactory progress. Imported cedar trees have grown to 40 feet, with a girth of 40 inches in six years, and that under imperfect conditions; there exists also an indigenous variety in satisfactory growth. English flowers, notably roses, and vegetables flourish well; in some instances improved, in others deteriorated by their change of home, but in the aggregate they

give gratifying results. The staple vegetable and fruit is the banana or plantain, of which there are a multitude of varieties. Pineapple, guava, mango, custard apple, Jack-fruit, limes, lemons and oranges have all fruited well in Entebbe.

In preparing a recent paper I was surprised to learn on expert opinion that botanically speaking no country was known to be so free from insect pests!

The Botanical Department, which has been so active in this branch of progress, has brought its statistical results up to date, and will be in a position to add greatly to the valuable information already supplied by it. The work of this department is one of extreme interest—the conditions which it encounters contain so many factors of an entirely new character. Uganda is situated precisely on the equator, yet has a climate ideally temperate, and a good rainfall (60 inches). Consequently there is a fascinating degree of uncertainty about experimental work, and a kind of medley is often the result, the produce of tropical and temperate climes frequently flourishing side by side, together with instances of peculiar modifications where distinctive characteristics have definitely adapted themselves to their surroundings.

In my belief in the future of this wonderfully fertile country I am anxious to see yet further exploitations of its resources by the development of a special agricultural department, established upon Board of Trade lines; one whose sole purpose will be to use, amplify and publish our knowledge in a manner suitable for purely economic purposes; for so far as is yet known it is agriculture that will be the backbone of commercial progress in these countries.

Minerals.

Indications have been discovered of the possible existence of minerals; indeed, to quote one instance, an eminent scientist has declared that the geological stratification of Unyoro, as judged by rock specimens, is practically a duplication of that in the Rand. But all mineral discoveries so far produce only conjectural results, and until these can be tested by geological surveys, succeeded by some practical prospecting, it is impossible to give any decided opinion as to the mineral resources. A great deal of the geological knowledge has so far been acquired in travel at the rate of about 15 miles a day and so, I assume, can scarcely be judged as conclusive.

Communications.

I suppose there is no country in the East of Africa better, if so well, intersected with roads of a passable character; certainly, considering its newness, there has been remarkable local activity in this particular direction, one which appeals strongly to me, so convinced am I that one of the greatest factors in the exploitation of any country is an effective opening up and maintenance of good communications. Throughout half of the Protectorate there must be 600 miles of roads, some practicable for wheeled traffic, all broad and well kept, and so safe and comfortable for ordinary foot traffic. Formerly the narrow winding paths which distinguish African lines of interior communications afforded opportunities for assaults from man and beast, and in the earlier days it was difficult to induce mail runners to travel at night, even as it is at the present day in remote districts. Now in Uganda and in the greater parts of Unyoro, Toro, and Usoga, it is most unusual to see a man with weapons of any kind, though naturally there is still need for solitary travellers to be cautious in the night; elephants, lions, and leopards being then active outside populous parts; the elephants more than ever so, the other beasts fortunately becoming scarce.

The increase of profitable trade is advancing at so substantial a rate that consideration is being given to the need for extending the railway to these countries, and practical tests have been applied to certain lengthy waterways with such success that the expediency of adding them to the scheme of communications is contemplated. Even when traffic is impeded by waterfalls, as in the case of the Ripon and Murchison Falls, compensatory advantages offer themselves in facilities for the conservation of force of considerable value. So pressing is the demand for an easy transport of the inland produce, that there is even a revival of old-time proposals for the clearing of the sudd from the channels of some of the swamps where there is sufficient depth of water.

Economic Progress.

A striking instance of progress is seen in the desperate efforts of the steamer authorities to keep pace with the growing volume of trade, efforts plainly manifest in the much-varying movements of the small fleet, accompanied by constantly-expressed longing for the doubling of that fleet. In reality these wishes are now in course of being gratified. You find that the

supremacy of Entebbe, the capital, as a port is rivalled by that of Kampala, and then, actually that of both by Jinja, which is in the vicinity of the outflow of the lake into the Nile, and is the official town of perhaps once the most belated country in the Protectorate. These facts may not mean much to the general listener, but to those intimate with local affairs it means three distinct strides in commercial and industrial development. What is it that causes all this? We find, on looking round, wagon loads of cotton, fibre, coffee, grain, hides and (so far in smaller quantities) rubber, native-made butter and coarse sugar, all making their way to the several wharves. We find these again are supplemented by natives carrying their loads to the stores to be later repacked for shipment; in fact, the produce exported from Uganda along the Uganda Railway during the last financial year reached a value of £107,000, a result already exceeded in the nine months of this financial year. The imports progress at the same rate, and it is cheering to reflect that the trade of the Protectorate must at the present day represent a sum of over £300,000 sterling. A further source of satisfaction is gained from the fact that revenue in the last financial year increased from £59,000 to £75,000, and that without including import customs to the extent of from £10,000 to £15,000, which, owing to the inland situation of the Protectorate, is collected at the seaport, Mombasa. Especial attention should be given to the further disadvantage which is temporarily suffered by these revenue figures. To foster agriculture, common products have been removed from the schedule of export duties, and to facilitate business in general other taxes have been reduced or abolished, particularly those upon the registration of porters, which in the days of difficult communication was necessary for the protection of natives engaging upon caravan work. Though the comparison of an actual gross revenue of about £90,000 against an expenditure of double that amount may not seem to offer much scope for gratulation, it is still encouraging to know that the era of progress is so far forward in a country where there was nothing to start from apart from what could be gained from trade in ivory, a trade now almost defunct. We can well assume that as since the completion of the railway, revenue figures are making real leaps by many thousands of pounds per year, very few years will elapse before the Protectorate can become at least self-supporting, enjoying at the same time all the gratification to be derived from a progress made, in respect to native interests, in studied conformity with humanity's best laws. This onward movement is not restricted as of old to Uganda alone—Usoga is forward, almost on a level with its leader—Unyoro and Toro are coming on with substantial help, and Ankole following a little behind. The Nile Province alone is backward of those under administration, which tardiness to a great extent must be attributed to its secluded situation.

Nothing whatever has been done in respect to the opening up of the Rudolf Province, so it lies for the moment somewhat outside the scope of this paper.

I admit to some feeling of disappointment with the small share British commercial enterprise has had in the development of trade in this Protectorate. Some month or two ago I read in *The Times* an announcement by a distinguished German, reflecting upon German colonial activity as compared with that of the British. To illustrate his view he instanced the Uganda Railway. Much as I would like to soothe my patriotic inclinations by accepting this statement without further question, I deem it wiser to face the truth, hoping to spur on effort by adding that last year's exports from German Lake ports to the Uganda Railway were almost equal to those from Uganda, notwithstanding the fact that we enjoy a great handicap in the more favourable agricultural resources of our territory. This is unpalatable, not because of the increasing volume of German trade, which we welcome, but in its significance of wasted opportunities. It is, therefore, great news to learn that British enterprise is at last moving to this field, and that large business undertakings are in progress to make use of opportunities offering no small promise of profitable return. This news will be agreeable to well-wishers of the natives, who are responding quite reasonably to calls upon their industry, and who, in Uganda alone, profited last year in earnings from a single company to the extent of £10,000.

Climatic and Health Conditions.

In dealing with countries of this character, it is fair that we should do so in full consideration both of their useful qualities and their disabilities. In the former category we have in the main parts of the Protectorate a perfectly genial climate, one which is ideal in its temperateness, its only fault being a lack of invigorating changes to cold. Except in abnormal circumstances, such as those in

the Nile Valley on the one hand, and the highest altitudes on the other, the mean maximum throughout the year is 77, the minimum 65. Is it not difficult to believe that in regions situated precisely on the equator the mean maximum temperature is from 10° to 16° below the records of the hot days of our own last summer in England? But then unfortunately there is no winter, and in the course of years the uniformity of temperature produces an enervation upon Europeans requiring at least a temporary change of climate to aid recuperation. It is this which makes one reflect as to the suitability of the country as a field for complete schemes of European settlement. There is no doubt as to the greater part of it being adequate for the purposes of planters—those who can afford to utilise and superintend native labour; but so far there is little encouragement for the hope that it will do for white manual labour. Speaking from the point of purely personal feelings, I am not greatly concerned at this outlook. The available native labour promises to be rich in skill and quantity, and among a people who are characteristically sensitive to class distinctions and prejudices and allow their fine discriminations to freely influence their conduct, I could foresee endless complications arising out of the presence of a white labouring class in the country.

But great work has been done in improving the hygienic conditions of the large centres. It is difficult to keep pace with the wishes of the able experts, even those who guide the administrations in their health-saving work in anti-malarial sanitation and such vital measures, so impatient are they in their great knowledge of the vast strides in that work accomplished by modern schools of tropical medicine. Yet remembering the numberless calls made upon governing bodies by departments, each loyally believing itself to be the hub of existence, it is sensible surely to expect that some degree of caution should be exercised before venturing upon large schemes put forward in full enthusiasm, promising though those schemes may be. I do not think there is reason to greatly complain of the advance made by the health department in such a sphere as that under actual administration in Uganda. Where our officers were liable to frequent and repeated prostration from disease, where one saw more or less pale and sickly spectres borne up by the glamour of pioneering which alone sustained them, now, notwithstanding existing climatic disabilities, your attention will be more readily attracted to sports clubs frequented by hale and hearty-looking men, consequently able in their improved health to do their legitimate work well, and in all ways to experience a real joy in living. Mosquito-proof rooms and anti-malarial municipal schemes generally recommended by the experts in tropical diseases have been introduced with remarkable success, and it is difficult to say to what degree of perfection those countries, whose very air once seemed poisoned, will one day be brought by a proper use of the rapid and marvellous discoveries of modern medical science.

I am anxious not to be dogmatic in my description of our Nilotic countries, as my experience in the rainy season was so favourable as to be contradictory of most reports of recent years, and so I concluded that it was necessary for me to repeat the tour under the less promising conditions of the dry season, before arriving at definite conclusions. As it was, temperate climate and beautiful green scenery, with an absence of mosquitoes, prevailed, once away from the Nile valley. My wife accompanied me even into the hinterland of these remote countries, and we both enjoyed perfect health throughout an extended tour. She has travelled with me over most of the Protectorate during the last seven years, and leaves with me again on Friday; so this statement may, perhaps, be taken as evidence of the sincerity of my, or rather our, conclusion that existence can be made at least tolerable in those parts of Africa. In fact, as a general indication of the health conditions, I should say that several ladies have proved by experience that the climate can be endured, and as that has been done on occasions under almost heroic deprivation of essentials of every day comfort (which is now avoidable, I am glad to say), it may reasonably be hoped that with a continuance of the present policy of co-ordinating principles of living there with those customary at home, there will be such an improvement in general health as to one day lift the country out of the category of unhealthy climes.

Of course, the natives are reaping their share of these great benefits, for fortunately the masses are outliving their old-time superstitious prejudices against our medicines and sanitary methods. To quote an example, I have myself been frequently a witness to the prevention of expected epidemical disaster by the wholesale resort of the natives

to vaccination. In such medical care of the natives the Church Missionary Society, with its very perfect equipment, does noble work, one which is nowhere more readily acknowledged than in the Government medical department.

Much is being done to educate the people in the prevention of other diseases, and in particular, and much to my relief, there is hope that the terrible rate of infantile mortality can be reduced by the abolition of habits opposed to all modern recognised health requirements.

Any readers of Ashe's booklet on "Life in Uganda" must have been struck with his account of the repulsiveness of the unsanitary habits of a people reputedly so greatly ahead of their immediate neighbours in neatness and cleanliness, and it must have been obvious that those qualities were merely superficial. This is now much changed, and with fitting supervision on our part quite a creditable advance in sanitation has been promoted in all the larger centres; to such an extent, indeed, have the principles been understood and appreciated that I have even considered the expediency of introducing in such a centre as Mengo a municipal system in which the native chiefs should be given, under guidance, a great share of responsibility. We have, however, to remember that with all this advance it has been found somewhat difficult to secure a full measure of co-operation from the chiefs and people in combating that dreadful scourge, sleeping sickness. I cannot well explain why it is so. With an epidemic such as small-pox there are instant symptoms and a speedy crisis, something more dramatic to appeal to the feelings, and so to incite instant activity in its eradication. In the more slow and mysterious disease, there is as yet little of a definite nature to grapple with, and the native is no believer in putting forth energy for a purely problematical return. The advanced chiefs are chary of hazarding their presence in affected areas, but the unsophisticated peasant, native-like, acts as if he were immune from a danger which does not present itself in a tangible form. There is no doubt whatsoever that when a cure is definitely proved the people will flock to avail themselves of it; even the reports of a promising experimental character are already attracting numbers.

I regret that I have little news of moment on this subject to add to that already public. It is known that the Protectorate has lost over 150,000 of its inhabitants by this disease. Various medical commissions have grappled with it, each with more or less degree of success in arriving at cause and effect, but in disappointment as to prevention and cure. Within the last few weeks our hopes were buoyed up by a rumour pointing to the discovery of a cure, but, as Major Ross indicated in *The Times*, there can be no solid foundation for any such report; for years, two at least I am told, are required for conclusive proofs. The truly satisfactory advance lies in the large expansion of the field of scientific research within recent times. The work of eradicating the fly by clearance of foliage shading water in the vicinity of largely inhabited centres, much frequented ferries and water supplies and such like measures is proceeding, but it is cumbersome, and is only practicable in limited areas.

Truly every one must join in an earnest hope that no matter who is to win the glory, a remedy and a preventative will soon be proved to be effective to stop the loss of thousands of lives which, natives though they be, are valuable units in the composition of a colony.

NATIVE AFFAIRS.

On this particular occasion I have devoted less space than is usual in direct allusion to purely economic details. This is due to two causes. One is the conviction that in the present and its succeeding years there will be a substantial introduction of commercial enterprise, which will require corresponding advance in matters of an administrative and general political character to secure a smooth and satisfactory course for the march of that enterprise. The other lies in the great interest which is at the moment being centred round native affairs, and it has been mentioned to me that views on that large question would be welcomed in quarters where the subject is given serious attention. It must be borne in mind, too, that a true and lasting economic prosperity in such tropical African countries as Uganda is completely dependable upon conditions secured only by a wise government of the natives. Let me mention labour as one of the most important instances. We in Uganda have some pride in the prosperous contentment of our natives, even though I have heard it said that the rate of economic progress there is not up to the possible standard, and is not, for example, up to that of the colonies further south. It is not for me to dispute that opinion, or to plead the advantages won in the South by the colossal influence of such a man as Rhodes, of the immense capital of such

an institution as its Chartered Company, and, as much as anything, perhaps, of the vicinity of the vast mining industries. I feel that it is something to be able to assert most emphatically that, if economic progress has been dilatory—a supposition open to contention—there has been no delay in the enlightening progress of our native races, and you may be sure that when economic prosperity does reach its highest standard, it will, if affairs follow their present course, have done so side by side with that of our natives and with their full co-operation.

It is upon this principle of consideration for the well-being of our native peoples that the governing policy is based. All the civilising forces of the Church and State recognise the wisdom of this procedure, and cordially harmonise their operations with that policy, and so with a kindly but firm insistence upon simple principles of probity in native conduct, and an almost extravagant observance of every requirement of honour and good faith in negotiations on our part, we are subduing the objectionable traits of their indigenous barbarism, and winning a strong confidence in the honesty of our purpose. In this the Missionary Societies loyally and cordially co-operate with the Government, and they have in those countries done a magnificent, and let us hope and believe, as we may, an ever-enduring work in the educational and moral upbringing of the natives; one which has been conspicuously serviceable in the sustaining of order through the very severe crises of recent years. The mutual advantages of this co-operation must be too obvious to be affected by such utterances as one occasionally sees in public print, calculated to create a rivalry for credit in the work of civilisation among those who have the privilege of sharing in it. It is well recognised that in Uganda, completely satisfactory results will be better secured by cultivating a spirit of inter-dependence; that this is so, can be observed in the admirable cordiality which marks the relations between officials and missionaries of the present day.

It is now my intention to devote serious attention here to the study of native affairs. I propose also to show that every effort is made to accommodate the accomplishment of our aims to the best trend of native thought and sentiment, and to avoid introducing reforms in a manner likely to needlessly offend native sensibilities. I have already stated that within the Protectorate, besides other divisions, there are four kingdoms—Uganda, Unyoro, Toro, and Ankole. Each of these countries is ruled by a king, aided by native councils, and is subject to a benevolent supervision by His Majesty's Commissioner or Governor, who is on ordinary occasions represented by the principal local administering or political officer.

In Uganda the present King, Daudi Chwa, is a son of Mwanga, and the fortieth of the line; a fact capable of proof in the existence of as many tombs, all having their history. He is only eleven years of age, and his powers are vested in a regency composed of the three leading chiefs. His education is the care of the Government. In Unyoro, Kaba Rega has been succeeded by one of his sons, Andrea, the fourteenth representative of a more modern dynasty. Kasagama, the King of Toro, is of a quite recent offshoot of the Unyoro line. Kahaya, the King of Ankole, represents a regime of about the same age as that of Unyoro. (In this case I am not so certain about my data.) All the reigning houses are believed to be of the same race (Bahima), and certainly are not of the aboriginal race. The Ankole local government has not yet reached the advanced stage of the others, and is at present in some disgrace, its functions being for the moment in partial suspension.

As Uganda is the pattern upon which the smaller kingdoms have voluntarily built their organisations since the inauguration of British control, I will describe, as briefly as may be expedient, the system upon which that country is now governed.

In the native capital there is an Audience Chamber, in which the King receives the petitions of his people, issues proclamations, and makes any announcements of a general national character. In this Chamber liberty of discussion is permitted at great length; a continuance of old custom, of course, improved, in procedure with the advance of education. Yet great caution is observed to preserve it from being advanced out of access by the humblest peasantry.

The King, himself, is directly advised in affairs of State by a native council, which is analogous in its duties to a parliament, but differing in its composition; membership being by appointment of the Council, and principally of chiefs of rank, supplemented to a moderate extent by private individuals of exceptional ability. This Council discusses all affairs of a national character, and includes within its range of duties decisions on matters of grave judicial weight, which are passed on from the native courts by appeal, or

by the native Chief Justice. It is this Council which the Government expects the King to always consult on affairs of local importance, and records are kept of the proceedings of all Council meetings.

There is next an institution called the Baraza, an Audience Chamber at which the King sits in joint presidency with the leading local political official. Here are heard and unravelled affairs which have puzzled the other Chambers, and petitions from natives believing themselves possessed of grievances against those other Chambers. There are also delivered announcements from the Government, carefully explained in all their detail. Opportunity is here given for the administering officer to educate the people in principles of local government, agriculture and general industry, and to get into and maintain intimate touch with the natives and their affairs. The influence which an able and tactful officer can exercise upon a country through this institution is enormous, and I hold that it is more by its establishment, and the confidence won by the open and frank discussion of affairs which it has encouraged, than by any other means, that the people have been brought into such contentment with our rule. It has ever been noted, that wherever the Baraza has been inaugurated, a fresh spirit of vigour has entered into the country, the natives feeling that through this institution they can share in the responsibility of government, even though it may be simply in the fact of their being able to keep conversant with affairs. In these Barazas, only the chiefs take part in discussion, and the order maintained is perfect. It is not difficult to imbue groups of these people with a fitting sense of propriety on such occasions; they always respond to judiciously-applied firmness. I wish it to be plainly understood that in the Baraza the wise political officer is seldom an obtrusive exerter of his authority. If he has well used his opportunities the chiefs will have become even too ready to lean upon him for guidance.

The same order, with only slight modifications, runs through the local governing bodies of the other kingdoms, and is being in principle applied to both the Central and Nile Provinces. In the kingdoms of the more advanced divisions, chieftainships are classified and registered, and their functions given definition. Records of all cases passing through the native courts are required so that proper supervision can be exercised over native judicial procedure. Some time must elapse before all this can be done in the more distant countries. However, there is a steady expansion of this organisation, from the centre, and where that occurs economic prosperity surely follows.

It is by means of such a system that great measures are smoothly put into operation. It is easy before framing legislation to gauge the beat of the native pulse, and to avoid such conditions as might unnecessarily offend native sensitiveness, or, as seldom happens, at least to impose them, if really essential, in the most palatable form.

The imposition of a moderate hut tax, for instance, has been managed with such mutual goodwill that the chiefs themselves advocated a like tax on bachelors, finding that a tax on huts alone led to unsanitary over-crowding, and bid fair to prove to some extent a check to marriage.

A great reform has been effected in the main principles ruling possession of land. Under the old rule practically all lands were the property of the State, which meant the King. Theoretically, the native Council had a voice in the settlement of land disputes which were nterminable, so complicated were the laws governing this question: in fact, about the only redeeming point in King Mwanga's reputation was his being the most able exponent of land laws in the kingdom, a reputation of ability difficult to reconcile with the imbecility of his follies. In practice, tenure was most uncertain, and a great impetus has been given to the agricultural industry by the conversion of fief tenure into freehold, there being created by this measure a strong community with settled permanent interests in the country.

Survey is being pushed on so that the delimitations of holdings may be defined and permit, with fitting precautions, of the diversion of unoccupied lands to genuine planters. The need of this is fully recognised, and measures are in progress for still further hastening the work.

In order that there should be full avoidance of complications in the tenure of the land, and to admit of harmonious adjustment of European and native titles to lands, a Commission has been at work for the better part of a year thoroughly investigating the conditions of native land tenure throughout the Protectorate, and it is proposed that upon the researches of this Commission, future land legislation shall be largely based.

Such complex laws as those affecting mar-

riage and succession have been, and are being dealt with. It will readily be understood that in a country hitherto under the governance of barbarism, the status of woman has required some amendment, and a better regulation of the state of marriage has had to be secured. But even these are simple as compared with the work of adjustment of property rights, and some time must elapse ere that question arrives at a completely satisfactory stage. It is, of course, difficult to suddenly adapt, with perfect results, advanced European laws so abstruse and far-reaching as those of succession to a country hitherto ruled by a comparatively simple totem system. Our legal advisers are fully alive to this, and advance is made with due caution.

To witness the able and intelligent discussion by chiefs, of questions such as these, and there are many such, is an enlightenment, and it is the improved state of mind brought to bear upon these discussions that marks one of the stages of the real progress of our influence. In this, and in a steadily rising grade of humanitarianism imparted into their judicial functions, we see a growing soundness of character of the utmost value in such a country's career. It is this intelligent and whole-hearted spirit which has marked the wonderful advance of Christianity in these countries, and it is with the fullest admiration that one sees the leading classes exert a substantial and practical interest in the immense native Church organisations, which, in the case of the Anglican Mission, are wholly self-supporting. Associated with these organisations, but in more complete control by the missions, are schools of various grades securing to succeeding generations highly educated chiefs and teachers and industrially educated classes to take their share in the material development of their country. Mission hospitals, great and small, alleviate the sufferings of thousands, and in several ways of like nature can the native feel the sincere sympathy and interest extended by the white race in its efforts to lift them on to a higher plane.

Some response to these efforts is apparent in the native character. Work has lost its native traditional indignity, agriculture is scarcely any longer a shame to manhood. Artizans are proud of their new sense of usefulness, while they know how to charge for it. I have mentioned that cotton and other plantations are spreading over the country initiated at our instigation, now expanding on simple commercial lines, that one sees loads of local produce approaching the chief centres. An appreciation of the better comfort attainable by industrial prosperity is seen in the increasing number of commodious brick dwellings in native precincts, and in the clean calico clothing which is so entirely ousting the filth-conserving bark cloth. House appointments are as yet rather primitive, but it is something to see the cleanliness and promising attempts at taste evinced by the better classes. It is also particularly interesting to note the march of education in the order entering into the keeping of records in chiefs' offices by young native clerks, using their typewriters with some proficiency. Their systems employed in compiling statistics may yet be crude, but they are not unpractical. Chiefs have begun to understand and utilise, to a moderate extent, the advantages of banking, and they are interested in industrial and commercial enterprises, in respect to which, after some lessons, they have acquired a wise habit of caution. The chief centre of all this new spirit is, of course, Mengo, the capital of Uganda, but it is spreading to Unyoro and Toro, is entering Usoga and Ankole, and with it all, the next five years should see a fine development in these countries of their commercial resources.

While the people are becoming more industrious of their own free will, I believe they are also more sober; in any case, there are no visible signs of that increase in real vice which is supposed to usually run concurrently with the advance of civilisation. I confess to being somewhat of a pessimist in respect to native sincerity, though optimistic perhaps as to ultimate possibilities in the development of native character, but after a fairly extended experience in East Africa, I can vouch for a reliability in the temperament of the natives of Uganda, Unyoro and Toro, which is as yet foreign to almost every other East African race. Whatever doubt may arise in the minds of sceptics as to how far action is guided by purity of motive acquired for education, or by simple self interest, the fact remains that the results are far above present rivalry from any neighbouring tribes. The most useful effects from this improvement in character are obvious in an appreciation of public interests and a steady abandoment of the habit of intrigue—the latter so rampant only five years ago, that it was impossible for a time in a country like Unyoro to obtain a collective expression of opinion on national affairs from among the chiefs—as is practically the case in the ex-

treme outer parts of the West and Central Provinces and in most of the Nile Province at the present day, all these being districts not yet brought within the effective reach of our complete control.

With an habitual tendency to believe in the efficacy of the policy of using the native chiefs to rule their country, and a consequent confidence in the principle of improving the character of the chiefs so that a corresponding improvement may be reflected upon the whole country, I have devoted most of my utterances to conditions principally affecting that class; and I wish it to be clearly understood that I maintain that so long as we refrain from being unduly meddlesome in the domestic affairs of the country, so long will the people be willingly amenable to the authority of the chiefs acting under our auspices, and to their improving influence as their education progresses.

I have presented a picture of a brightness the existence of which is indisputable. Yet with those who are intimate with the undercurrent of native thought, and are mindful of native history, the conviction remains that even amid all this glamour, it is still wise to maintain a policy of constant prudence, making sure that the reins of responsible control shall not in one whit be slackened.

We know that only a few years since these races were utterly at the mercy of the whims of capricious chiefs, to whom life was of no value. Hundreds of human beings would be slaughtered or many mutilated in a momentary fit of kingly vexation. Chiefs would slit a nose, cut off lips, lop off a limb merely for the accidental spilling of beer or the appearance of a hair in their food. It is the people accustomed to such treatment whom we have suddenly emancipated. It may be said, and said with some truth about many, that surely there must be gratitude for the relief from the dreadful oppression of the serfdom which characterised former days, and for the blessings of peace and prosperity which have now entered into the country. But let us look at the circumstances from all points of view. These people are emotional, they are conceited almost beyond belief. They have a dread of monotony, even a prosperous one, that is so lacking in any common-sense as to be inconceivable by the majority of our race. Stanley, who acquired such a friendly feeling for the chiefs as to have maintained a correspondence with the leaders for over 20 years, and spoke only four years ago in this hall in sympathetic interest with the people generally, described them, taken as a whole, as being crafty, fraudulent, thievish, deceitful, lying knaves; predatory, with a more developed instinct of lawlessness than any other African tribe. He goes on to say, that according to their opportunities they are heady, despotic, vain, sycophantish, from the great chiefs down to the peasant with a child to carry his gun. Truly, the writer must have been angry when he adopted this phraseology, even though he tempers it by allowing that they are neat, clean, and modest. Yet I have myself had moments, in more recent days, when I sympathised with his command of language!

Years later Colonel Lugard, whose friendly interest is indisputable, characterises them as indolent, affectionate, at times humane, with a tolerance towards lying and thieving; cruel, treacherous, and impulsive, one moment brave in their conceit, the next liable to reasonless panic.

"At one moment the countryside looks the home of endless peace; unarmed men and women are engaged in agriculture, or chattering over their wares in the market. Five minutes later some wild rumour has passed through the people like an electric shock, and, without heed to its truth or falsity, the war drums are sounding, and every hill and dale bristles with spears and riflemen. The friends of a moment ago are ready to take each other's lives."

These expressions have been used with especial reference to Uganda, but the same, with various modifications, can be well applied to the other countries. Now, splendid as have been the instances among them of moral and intellectual development, we cannot believe that these people have in such a very short time of peace and prosperity utterly and permanently changed the very base of their national character. Truly, the serfs of yesterday have generated, under our fostering care, a sense of liberty, and a corresponding attitude of independence, but they have also developed a jealous sensitiveness, and are prone on the slightest provocation, and when they think it safe, to indulge in objectionable insolence. They being conceited, is it to be expected that their progress has made them other than even more bumptious?

All raw natives, almost without exception, have their moments of aberration, of succumbing to unreasoning moods, moments which they themselves often deplore, and it is those moments that every administration should be prepared for, confident in the case of the more enlightened districts that once tided over

the very culprits themselves will be the most grateful for having been protected against themselves. This is the crux of the question. We are the superior race by virtue of our ability to teach and to restrain, and the natives readily acknowledge this, as they readily throw themselves upon us for the responsibility of judgments in decisions in all grave crises, and will continue to do so until generations of civilisation remedy their mental defects, or we gratuitously or out of mistaken sentiment throw them entirely upon themselves. Natives under a wise restraint can be like good and even clever children. Natives in their wild impulses and with passions aflame can be very devils incarnate.

Within my experience, on more than one occasion, even a Regent has stood up in the Council and, in reply to my regret at having to reprove the chiefs, has said boldly that when the restraining hand is withheld from them then will Uganda decline, "for," he would add, "we are but as children, well-meaning mostly, but at times woefully wilful." Public expressions of this sort are not to be ignored, for Uganda chiefs have their pride and much of it, and do not readily waive their dignity in such admissions.

On this native question I know what I am talking about. Our Chairman himself will, I am sure, bear me out, that many have been the crises in which a knowledge of native character, and the need to control it, has enabled me to save the situation. I break my rule of personal reticence in this manner because I feel the subject is a serious one, and know that there is a kind but yet mischievous public sentiment growing in favour of the extension to natives of a liberty of self-control for which they are not yet ripe, and which would only be the cause of their undoing. Let us go on educating them gradually up to a sense of their responsibilities, guiding them in their work of governing their countries, sustaining them when their energies flag, as they often do, commending them when they do well as they yet more often do, but ever firmly retaining an ascendancy. If we lose that ascendancy, we might then leave them to their own natural devices, capable of buying, selling, slaying, or robbing each other; even, at their worst, of slashing open the bodies of captive women, impaling children on spears, everything that is horrible and evil, and all of which they have done less than ten years ago in the very countries we are now dealing with, and as they are still quite possibly doing when passions get loose in the countries outside the limits of our influence, and will so do until we extend a hand to bring them under our care. I think that you will agree with me it is wise that we should go on with our work on our own lines—a work already so fruitful of the blessings of peace and order. And in this connection I am able to say that excepting in the case of a dispersal of a predatory band of mutineers only one punitive expedition has taken active measures since 1899, a period of eight years; and in that instance it was to demand retribution for wanton murder by an outlying tribe.

There is a large class rising from among the people seemingly entering upon an entirely new phase of life, one showing every indication of a moral understanding made extraordinary by its surroundings and by the country's own past. With judiciously expended sympathy and support this class will still expand and bring the country on to a higher plane of usefulness.

Conclusion.

I have cause to be proud of the honour to-day gained by Uganda, the subject of my paper, in the presence of so distinguished an assembly of gentlemen directly concerned in the evolution of that section of the African Empire. Its history is incomplete without the name of Sir George Mackenzie, who pioneered in person the inauguration of the great scheme so long before conceived by Sir William Mackinnon. We have Sir Frederick Lugard, so appropriately our chairman to-day, as the founder of British authority in Uganda. With these there is Sir Clement Hill, who, as Superintendent of the African Department, so long represented the mainspring of government, and then Colonel Hayes-Sadler, who so recently relinquished the Uganda Commissionership with the satisfaction of leaving the country on the safe road to economic prosperity. I glance further towards Bishop Tucker, for fifteen years the chief representative of Church Missions in their historic African work, and a cordial friend of every Uganda administration. Truly such a gathering is a distinction.

I have at times used bald language to press home in your minds comparative pictures of the barbarous past and the bright and promising present, and I earnestly hope that I have succeeded in convincing you that under a governing policy of a benevolent control, in sympathetic alliance in countries which have

nationally adopted Christianity with that of a tolerant and Christianising training and education, there is no mean tale of progress to unfold.

DISCUSSION.

The CHAIRMAN said he was sure the audience would accord a very hearty vote of thanks to Mr. Wilson for his interesting and suggestive paper, and he thanked him personally for the very kind way in which he had referred to himself. Contrasting the picture of Uganda, as drawn by the author, with what it was when he (the Chairman) knew it, the progress shown to have been achieved was a proof of the ability of our race to meet what he thought to be the great question of the twentieth century—the development of the tropics, with a view both to the good of the natives inhabiting those countries, and also to the increasing wants of European nations as far as raw materials for manufactures were concerned. The first part of the paper had been devoted to the early history of Uganda, to the days when Speke first discovered it in 1860, or thereabouts, and it might, perhaps, be interesting if, for a moment, he recalled some of the conditions under which Uganda came to be British. It was sixteen and a-half years ago since he received orders to proceed to Uganda, and make a treaty with its king and people, and endeavour to bring it under British control. It was not an easy task, for Dr. Carl Peters had already preceded him with a view to annexing it to Germany, while Emin Pasha was coming from the south-east, and was understood to have similar instructions. However, he (Sir Frederick Lugard) reached Uganda, and succeeded in making the treaty, but he could not forget Christmas night of 1890, when passions ran very high, and it seemed to be touch and go whether their little force would be attacked and exterminated, or whether they should succeed in their object. However, with the help of what was called the British, a party which was at that time much the smaller of the two hostile factions into which the country was divided, they succeeded in obtaining the treaty, and for the next year they devoted themselves to trying to solve the main difficulties between the two parties, and to bring peace into the country. During that year they succeeded in bringing the third, or Mohammedan party, into the country, who had been, as it were, outlaws on the frontier; and they also brought down a body of Soudanese soldiers who had been left by Emin Pasha in his equatorial province, and who, being without a leader or master, were doing terrible damage by raiding the whole of the country in which they temporarily found themselves after their exodus from the Sudan. Those men were brought back to Uganda, and they formed to this day the nucleus of the troops with which the country had been held. Towards the end of 1890 it seemed as though some real kind of progress had been made, and that the two hostile factions were beginning to settle down in peace, when suddenly a spark set the whole ablaze, and before they knew where they were the two factions had flown at each other's throats, and their little party, together with the English faction, had to defend themselves against attack. It seemed at first as though all their hopes and all their efforts of a year had resulted in complete failure. But looking back by the light of after events it was, he thought, perhaps, the best thing that could have happened for the country, because such a warlike and excitable race as the Waganda would never have settled down in peace until it was decided which was the stronger of the two parties. Again they set themselves to the task of endeavouring to promote peace and settlement in the country; and as they were progressing, as they thought, from a state of turmoil and war, a still heavier blow fell, for he received a letter from the Directors of the Chartered Company, whose agent he was, to say that its funds would no longer permit of their retaining Uganda, and that he must make what dispositions he could, and evacuate the country. It was a hard blow, and he hardly knew what to do. But he did not carry out his orders, and stayed on. He had the thorough sympathy of the Directors of the Chartered Company. It was not their fault that funds did not permit of his remaining, and the British Government would not give it the assistance required in order that the Company should retain their position. Sorrowfully, therefore, in June, 1892, he turned his back upon Uganda and came home to England, to start a fresh campaign of a different kind,—to fight for the retention of the country. Most of those present had, no doubt, forgotten what a sharp campaign that was; the debates night after night in the House of Commons, and Mr. Gladstone's fiery eloquence. It seemed at that time as though it were a losing cause; but Lord Rosebery, the Foreign Minister, stood forward as the champion of Uganda, while England and Scotland spoke out unmistakeably in favour of redeeming the pledges which had been made to the people and those who had fought on our behalf, and retaining under the British flag the country which had become British, and not allowing it to be absorbed by Germany. Thus the campaign was won, and Uganda was retained. In the second part of his paper Mr. Wilson had dwelt upon the accessibility of the country, and had alluded to railway extension. The retention of Uganda was synonymous with the construction of the railway to get to it. In fact it was practically impossible to retain the country without such a railway, because the cost of transport was so enormous. When they tried to place before this country the reasons why Uganda should be retained, they pointed out its extreme importance, at the sources of the Nile, to Egypt and the Sudan; they showed that if that country fell into the hands of another power the control of the waters upon which the vitality of Egypt depended would pass beyond our control; and they spoke, also, of

the extraordinary possibilities of the country, its productiveness, and the salubrity of its climate. He himself was considered an enthusiast; but his words were nothing like as strong as those he had heard since from men who had gone and settled in the country. He had been told by some of these that the climate of East Africa was unrivalled on the face of the earth; but of couse, the area in which that fine climate obtained was a small one. Nairobi, the head-quarters in East Africa, could now boast of a large population, whilst there were many hotels and other buildings. Only yesterday he received a copy of the newspaper published there, in which one column was devoted to the local advertisements of shops, whilst another column was filled with the list of distinguished visitors staying in one single hotel. Altogether the progress and the conditions of life at Nairobi appeared to be better than were ever even anticipated in the old days. A deputation recently waited upon the Prime Minister with regard to African railways, and he had said, in reply, that in the Uganda Railway we had an object-lesson of how not to do it. But apparently the overwhelming calls of his high office had prevented the Prime Minister from studying the latest statistics of the Uganda Railway, and he must have been rather alluding to the general belief of a year or two ago, when there was a prevalent pessimistic view that they had made a great mess of the Uganda Railway. But what were the facts regarding that railway to-day? It had, as was known, been completed but a few years. And though, perhaps, the initial capital expenditure on the construction of the line was greater than it need have been, the fact remained that to-day the railway was not only paying the whole of the working expenses, but was already returning a dividend upon that large capital. The dividend, though at present a small one, was yearly increasing. There was, he thought, every prospect of the Uganda Railway turning out a really valuable national investment of capital. But an undertaking like that must not be dealt with on its mere merits as an investment. Germany and France had found it worth their while to subsidise their colonies to the extent of several millions a year, without expecting any interest on their capital, because there were in those countries raw products in the shape of cotton, fibre, and rubber, which were so valuable to their industries. England, also, was paying annually certain grants in aid of some of its Protectorates, not very large in amount compared with Germany or France perhaps, but on these grants we were not looking for any return at all in actual dividends. There was in the Uganda Railway an investment which bid fair to prove a really good one, while, in addition, it was giving assistance to British trade and industry in the ways which had been described by Mr. Wilson in his paper. He had received that morning a letter from Sir Charles Eliot, who until quite recently was Commissioner in East Africa, regretting his inability to attend the meeting, and quoting some figures he received only a day or two ago from East Africa, which showed that within the last two years the imports had doubled, and that the exports had more than doubled, while the receipts of the Uganda Railway had increased from £124,000 to £222,000, which was very nearly double. He thought these statistics were very pertinent to the subject of the paper, because, although the railway did not actnally enter Uganda, it was the main artery upon which the whole life and vitality of that country depended, and which alone afforded it a chance of expansion. Mr. Wilson had told them, and it could be also seen from the Blue-books concerning Uganda, that the Protectorate had doubled its imports and exports within a period of three years. The author had also referred to the railway freights, and told them that from Uganda to the coast, and *vice versa*, they varied from £3 to £15 a ton, and that the cost for special articles was very much more than that. Calculating the distance as 720 miles, though it was really over 800, that worked out at from one penny to fivepence per ton mile. Those rates seemed to him very high, and with all due deference to experts, he thought that if they were somewhat reduced, it was very probable that there would be greater progress and equally large returns for the line. We had heard that such enormous quantities of produce were pouring in for transport, that the steamers on the lake could not cope with them, and large accumulations were taking place. If, therefore, the reduction of freight rates by the railway should result in a traffic greater than it could compete with, it would be a very strong argument in favour of doubling the line, which many were now urging should be done. He thought it was the duty of the person to whom was accorded the honour of presiding at a meeting, such as this, to crystallise into such a form as might remain in our memory a few of the facts which the wealth of the expert knowledge of the author placed before us, and to draw from them a few useful conclusions. With regard to the Uganda Railway, from the facts before them, he thought he could say, without fear of contradiction, that a policy of well-considered extension was quite justified—a policy of gradual extension onwards towards the Albert Lake, to tap the shore of that inland sea, and a policy of constructing small feeder lines which might bring additional cargo to the main line, and develop new areas. It had been a great pleasure to him to hear what extraordinary progress had been made in Uganda. No doubt there were some present who would remember that in the controversy which arose at the time of the controversy as to the retention of Uganda, Mr. Labouchere made great sport of an accidental phrase which he (the Chairman) made use of when he said that the people of Uganda were so progressive that they wanted rat-traps and white donkeys, and ridiculed the economic progress of people who wished for such things. To-day the people were wanting type-writers and account books! Mr. Wilson, he was glad to say, had given just praise to the

mission agencies, which had done an enormous work in Uganda, and, looking at the matter from an administrative point of view, had relieved the Government of the great problem of education. Mr. Wilson had also eulogised the research work done in Uganda in connection with sleeping sickness and the study of malaria. No praise could be too great for the devoted men who had risked their lives in the areas which were subject to sleeping sickness, and he hoped that their efforts would soon be crowned by some practical results. In the meantime, however, he thought that there were certain lines upon which the Administration itself might do as good work as scientific experts. Speaking from long experience, he believed the greatest mortality in Africa was caused by infantile enteritis, due to the insanitary condition of the native towns, and the contamination of the water supply. It was quite within the power of the Government to tactfully bring pressure to bear by which those conditions might be improved, and the lives of an enormous number of young children saved. Another great drain upon the population was the small-pox scourge. That, again, was under administrative control, for, if the medical officers vaccinated the people of their districts, the disease would be stamped out. He would conclude his observations with one or two remarks upon the latter part of the paper, for it was that portion which, to his mind, was the most interesting, as it gave them a glimpse of the machinery by which all this progress had been achieved. They were told that the affairs of the country were discussed in a native council, presided over by the king; membership of it was apparently by co-optation; and it was apparently invested with judicial power as an appeal court, from the native courts and the "native chief justice." Perhaps Mr. Wilson, in his reply, would tell them something about the native courts, and of whom they consisted, what powers were entrusted to them, and whether they included the power of passing a sentence of death. It would also be interesting to know whether the decisions given by the native council were subject to any sort of review by the British administration. He should like to know, too, of whom the Baraza, which was under the joint presidency of the king and the local Administration, consisted, and how they were elected. Was it a national assembly, like the old Saxon Witenagenmot, at which every free man could attend, or was it constituted by any form of election? He should like, also, to have further information as to the hut tax and the bachelors' tax, for it was not quite clear to him why the hut tax had proved to some extent a check to marriage. The brief remarks of the author about the conversion of fief tenure to individual tenure were, of course, of great interest, for it had always seemed to him that the real emancipation of the natives consisted in the recognition of individual ownership, which meant individual responsibility. It was no use liberating people wholesale from serfdom or slavery unless their individual responsibilities to the State were simultaneously recognised.

Sir Clement L. Hill, K.C.B., K.C.M.G., M.P., said he wished that somebody else had been called upon to speak at that moment, because, besides the eminent administrators he saw in the audience, who had already been mentioned, there were present men who had worked in Uganda, and who had contributed very largely to the control of the country and to the development of its resources, such, for instance, as Colonel Coles, who commanded the troops, and Mr. Whyte, who laid out the Botanical Gardens. He could only suppose that he had been called upon to speak because he had been so long connected with the Foreign Office, and he was proud to think that he had been associated with the affairs of East Africa since the days of Sir Bartle Frere. He went out in 1872 with Sir Bartle Frere to put an end to what was then almost the only East African subject that interested England—the slave trade and slavery. He was glad to think that it was left to him to mention that subject, for it had not been referred to either in the paper or the Chairman's remarks. The fact that slavery and the slave trade had not been referred to was, he thought, a very great mark of the success of the past work of the Government. The slave trade and slavery were a thing of the past, for England had succeeded in putting it down. He believed that the Chairman, Mr. Wilson, and the Governor of East Africa (Colonel Hayes Sadler) would corroborate him when he said that slavery had practically died out in East Africa. That they owed to those great pioneers of civilisation who had risked their lives and given the best of their days to the work. Sir Frederick Lugard had risen to his present position by no armchair work, but at the risk of his life. The Chairman had not told them why it was he was sent to Uganda; and very few present, perhaps, remembered that it was because when he came up as a junior captain of the Norfolk Regiment from South Africa on leave, he found that in Nyasa the people were in great extremities, were being oppressed by slave traders, with no military man to help them. It was then that Captain Lugard joined them. He was twice wounded, and took part in the attack upon Mlozi's forts. He saved the situation there; and it was largely owing to his work as a soldier, and not at all as an Administrator, that we now held British Central Africa. Mr. Wilson, too, owing to his great modesty, had omitted to say that it was very greatly due to him that the English held Kampala when Major (now Sir Charles) Macdonald, suppressed the mutiny of the Soudanese troops. Mr. Wilson had assisted in keeping Uganda quiet, and was rewarded, he was glad to say, with the C.B. which he now wore. There was one lesson he hoped those present would carry away with them: the need for great patience when considering the actions of Administrators in the wilds of unknown countries.

It was easy to criticise them and to write letters to *The Times* and other distinguished newspapers, and to raise an outcry against them and ruin their career simply because somebody might say that this, that or the other man had committed an indiscretion at a moment when nobody knew what the circumstances or the surroundings were or how difficult the position in which he might be placed. Others would impress upon them lessons of commerce, lessons of geography, and lessons upon other things; but as having been connected with the administration of those countries for nearly 40 years, he would ask them to bear in mind the fact that they ought always to give credit to the man on the spot for knowing what he was about, for having some reason for his actions, and for at all events being imbued with the best intentions and best wishes for the honour and glory of England and of Great Britain. He would conclude with the words of the motto of the Colonial order, "*Auspicium melioris ævi*," we had seen in Africa the dawning of a brighter day.

Bishop TUCKER said he might be forgiven if, as representing the Anglican Church of Uganda, he confined his remarks simply to the work of the Church there. In 1890, when Sir F. Lugard entered the country as representative of the British East Africa Company, there were but some 200 baptised Christians in Uganda; to-day there were over 60,000. Then there was but one place of worship, a tumble-down shed, which was dignified by the name of a church. To-day there were 1,700 places of worship scattered throughout the Protectorate, ranging from the little country church which would accommodate possibly 20 or 30 worshippers, to the great Cathedral church of Namirembe, which would hold a congregation of some four or five thousand. All those churches and the school-houses were built, maintained, and repaired entirely from native sources. When Sir F. Lugard and he first met in Uganda there were, he supposed, some five or six natives engaged in the work of teaching their fellow-countrymen. To-day there were nearly three thousand men and women engaged in carrying on the work of the Church, of which thirty-two were native clergy, maintained also from native sources. Then, there were some seventy communicants; now, there was a noble band of some sixteen or seventeen thousand. Then, there was for the purposes of education but a little handful of children; now, there were in the elementary schools some 24,000 under regular instruction. With all his heart he believed that the people of Uganda had a right to share in the administrative, industrial, and commercial life of their own country; the Church was, therefore, throwing all its strength into educational work, so that the people might be thoroughly well fitted to play their proper part in that life. Besides the elementary schools there was at present a very remarkable educational experiment being made, which was nothing more nor less than a high school which had been formed at Mengo, intended mainly for the sons of chiefs. It had been found that amongst the most neglected lads of the land were the sons of the chiefs, their fathers being most unwilling that they should associate with the sons of the peasantry. A high school, therefore, had been formed for them, and at the present moment there were 130 sons of chiefs, or young lads who were themselves chiefs, but minors; the idea being that they should remain entirely in English hands for something like three years, being thoroughly taught and trained on the public school system and under house masters. From there, they were passed into a higher intermediate school, which was founded upon the hill of Budo, hard by Mengo, and there they stayed for another three years. What the effect on the future of Uganda was likely to be when those 200 young chiefs, as they hoped the number would soon be, went into the country to take up their government, and carried into their administrative life and their chieftainships, that which they had learned in those schools could well be imagined. That, he thought, was one of the most interesting developments of the educational work at present in hand, and he looked forward with hope to the foundation in the not distant future of some collegiate establishment, some university, to which the intermediate school would serve as a source of supply. He believed that they had before them in Uganda a future bright with hope, and that they would find that from Uganda there would radiate north, south, east and west, an influence which would tell on the well-being and uprearing of nations in the surrounding countries.

Mr. SIDNEY GOLDMAN said his acquaintance with Uganda was very slight, and extended only to a trip which he had recently made, and from which he had only just returned. During his trip opportunity had been afforded him of forming certain distinct impressions as to the possibilities of the country, which he might describe as being in the zone of the Congo, and as the heart of British Africa, not only in a geographical sense, but also, in time to come, from an economic standpoint. Mr. Wilson had told them that the administration was devoted to spadework, in other words, to the process of civilisation, and had admitted that under the benign influence of Church and State a great impression had been produced upon the native mind. He hoped the Church and State would further co-operate in the direction of bringing about a consciousness in the mind of the native of his value as a worker, because in that, he thought, lay the solution of the economic problem of Uganda. He did not believe, nor did he think anyone who had been in the country would contradict him, that Uganda was a white man's country, or was ever likely to be. It was, indeed, essentially a black man's country. He did, however, believe that there was great scope for the white man in certain directions, namely, in

taking places of instruction and laying out plantations, and more particularly in trade and commercial matters generally. In that direction he thought white man's labour would be extremely useful. Mr. Wilson had complained of the lack of commercial development in the country, but he did not see how that development could take place until the land question had, once and for all, been settled. It had been the policy of the late Commissioner, Colonel Hayes Sadler, and it was the policy of the present Commissioner, to push that forward, and limit the boundaries of chiefs and kings as quickly as possible. Until it was known what residue of the land was available, he did not see that much commercial enterprise could be expected. Mr. Wilson had drawn attention to the value of the opening up of trade by regular trade routes and the making of roads. If the Colonial Office would only take courage and assume a more forward policy, such as had been adopted by the railway in British East Africa, and extend the line from the Lake northwards, not only from a strategical but from a commercial point of view, great advantages would accrue. He had been studying the German papers lately, and they were quite envious that the trade from Nyanza should be taken by a British railway, and they were clamouring for a railway of their own. The sooner a railway was constructed to the Lakes and the trade for Uganda so secured, the better. Feeder lines would then follow the natural course of the Nile. He had quite recently listened in that hall to a very interesting paper on "The Cape to Cairo Railway," and he would specially like to call the attention of those present to a likely line of communication between Alexandria and Mombasa, *viâ* Uganda. As a glance at the map would show, the country was admirably adapted for it, for it was intersected by the arteries and veins of a perfect water system, with falls which could be utilised for the generation of electric power. Sir Clement Hill had referred to the great work which had been done by the staff out there, and if Mr. Wilson, when he returned to East Africa, would carry the sense of the meeting that that work was deeply appreciated, he was sure it would be a great encouragement and incentive to them in the future.

Mr. WILSON, in reply to the Chairman's remarks in reference to the Courts, observed that the Uganda Courts were controlled by the Uganda Agreement, whilst in other parts of the Protectorate the Courts were controlled by native court ordinances. Under these the chiefs could inflict penalties up to five years. All the sentences were open to revision, and, as he had mentioned in his paper, the records of all cases were sent to head-quarters. With regard to the Baraza, its members were the leading chiefs, county chiefs as they were called. With respect to the labour question, referred to by Mr. Goldman, he had mentioned in his paper that in one town alone a congregation of from 3,000 to 5,000 labourers might be seen ready for work every morning. The land question was a troublesome and vital one, and was difficult to appreciate. But quite recently a special commissioner had been sent out to superintend all the survey questions throughout the protectorate. In conclusion, he begged to thank the audience for the very cordial greeting which he had received.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Wilson, and the meeting terminated.

EIGHTH ORDINARY MEETING.

Wednesday, January 30th, 1907; SIR WILLIAM BOUSFIELD, M.A., LL.D., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Fazl, Shaikh Abdul, M.A., LL.D., Jullundher City, Punjab, India.

Green, George Arthur, Public Works Department, Poona, India.

Hartshorne, William Davis, Methuen, Massachussetts, U.S.A.

Henton, Samson Baskcomb, Boys' High School, Rondebosch, Cape Colony, South Africa.

Hough, Warwick M., 902, Rialto-building, St. Louis, Missouri, U.S.A.

Litten, John George, F.S.A.A., 241, Pitt-street, Sydney, New South Wales, Australia.

Naftel, Cecil Oakley, 20, Eastcheap, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Amsberg, Simeon Ernest, Penang, Straits Settlements.

Bose, Asok, University, Birmingham.

Braithwaite, James E., 6, South-parade, Leeds.

Burt, Andrew, M.I.M.E., M.Am.I.M.E., Fleetshouse, Tranent, N.B.

Buyzer, Charles Allan Oswald, F.S.I., 128, Hultsdorp-street, Colombo, Ceylon.

Campbell, William Archibald, 144, Warren-avenue, Chicago, Illinois, U.S.A.

Chaussé, Alcide, 1051, St. Hubert-street, Montreal, Canada.

Dadachanji, Rustonshaw K., B.A., LL.B., Kalbadevie-road, Bombay, India.

Edwardes, Stephen M., Highfield, The Ridge, Malabar Hill, Bombay, India.

Emslie, B. Leslie, Dominion Agricultural Offices of the Potash Syndicate, 3, Holbrook Chambers; 104, Sparks-street, Ottawa, Ontario, Canada.

Hogg, John, 13, Paternoster-row, E.C.

Humphries, Albert Edward, Balfour-rd., Weybridge.

Johnston, John, B.A., The Villiers Endowed School, Limerick.

Kamm, Director, the Rigibahn, Goldau-by-Zurich, Switzerland.

Khan, Ahmad, Hosain, B.A., Sessions Court, Jhelum, India.
Law, J. A., Birkbeck Bank-chambers, Chancery-lane, W.C.
Middleton, Professor Thomas Hudson, M.A., Board of Agriculture and Fisheries, 4, Whitehall-place, S.W., and University, Cambridge.
Pennant, Claud Douglas, 2, Mitre-court-buildings, E.C.
Rowntree, Bernard, 20, Queen-square, W.C.
Schenck, F. E. E., Studio, 1A, West-street, Pimlico, S.W.
Seaton, Miss Ellen Jeannette, 93, St. George's-square, S.W.
Tatsuno, Professor Kingo, M.E., Imperial University, Tokyo, Japan.
Tyler, William Ferdinand, Royal Societies Club, St. James's-street, S.W.
Wilson, Fred., 24, Palace-gardens, Enfield, N.

The CHAIRMAN, in introducing the reader of the paper, said that Mr. Parsons had been brought to the consideration of the question of apprenticeship by finding how very many of the children who left the Board Schools went out into life and obtained work which taught them nothing, and which, a little later in life, landed them in an out-of-work condition. Mr. Parsons would approach the subject largely from the social side, which all who had been brought into contact with the County Council and elementary schools generally, or with the poor subsequently when they were out of work and needed assistance, knew was a serious and important one.

The paper read was—

APPRENTICESHIP.

By JAMES PARSONS, M.A.

It is proposed in this paper to give an account of the objects and work of an Apprenticeship and Skilled Employment Committee, and to add such comments as suggest themselves. The work is concerned with the industrial training of boys and girls who leave the public elementary schools. It has its root in a wide-spread conviction that the welfare alike of the individual and the community demands an increase in industrial efficiency, and that the means of improvement is to be found in the better training of the young. The education of boys and girls in preparation for their working life primarily concerns the parents, interested in the future of their children, and the managers of industry, interested in the efficiency of labour. These are the responsible persons. The matter nevertheless is one in which charitable persons who seek to improve the social condition of their poorer neighbours may play a useful part. The scheme is based on ideals which are clear and coherent.

Industrial training ought, it is thought, to be undertaken with definite regard to the prospects of the boys and girls when they have grown into men and women. Thus the selection of a trade by parents for their children should be guided by the promise which it affords that those who have learnt it will find in it regular employment, under suitable conditions, and at reasonable wages. It is, furthermore, of importance that the training of the children should be such as to turn them out artisans, instructed in their trade as a whole, as distinguished from those who know a portion of it only, and from "wasters" who know no part of it thoroughly.

The training, moreover, should be favourable to the habit of regular industry, and to a healthy growth in mind and body; while the conditions under which it is undertaken should be fair both to employer and employed. The fulfilment of these purposes demands an equipment of industrial information, not only with respect to the openings from time to time offered by employers to young people, but also on the past history, present condition, and future prospects of the several trades. Of such knowledge there cannot be too much.

An important feature of the scheme remains. It is sought to form a solid body of opinion on the propriety of securing a good start in life for young people, and to concentrate on this object the efforts of all those who in the home, the school, the office, the workshop, or the Council chamber, are in a position to aid in its accomplishment.

The experience of the writer has been gained in London as a member of the Whitechapel Committee of the Charity Organisation Society, which has carried on this work for the past 3½ years through a skilled employment sub-committee. This committee is one of a group of agencies which have sprung up in the last few years in order to carry out the objects which have been sketched.

It may be of interest to note the sequence of events out of which the work in Whitechapel grew. Efforts had been made for seven years previously to promote thrifty habits among the poorer inhabitants of the Whitechapel district. These efforts met with scanty success. The committee concluded that the low earning power of many of the inhabitants made it difficult for them to protect themselves against risks in the future at the expense of claims in the present. The committee turned to the promotion of skill in employment as a remedy for industrial inefficiency. The scheme, more-

over, promised to be remedial of specific evils, as will appear subsequently. It was sought in particular to strengthen boys and girls on leaving school, and their parents, to resist the pressing temptation which the conditions of trade in London offers, and to prefer hard work and low wages in a promising trade to high wages and an easy life in prospectless employments.

Advice was accordingly sought from those who had experience. The Jewish Board of Guardians had carried on the work of apprenticeship through their Industrial Committee for about forty years. Members of that committee gave timely help by generously placing their experience at the disposal of those who proposed to undertake the work. The procedure which will be described is a close adaptation from the practice of the Jewish Board of Guardians. Two other agencies should be mentioned. The East London Apprenticeship Fund had for seventeen years past carried on a similar work, assisting parents by loans to provide the necessary premiums. They had thus accumulated valuable experience. It was proposed as regards this and all other agencies to work as far as possible through those already on the ground. The Apprenticeship Committee of the Women's University Settlement in Southwark had also for seven years been engaged in apprenticing physically-defective children and the children of widows. A paper embodying this experience, prepared by Miss M. K. Bradby and Miss Durham, was read to the Council of the Charity Organisation Society in May, 1903.

The procedure adopted by the Whitechapel Committee will be now briefly described. Applications are entertained in respect of children whose homes are in the area covered by the Whitechapel Poor Law Guardians, or who attend a school within the area, other than Jewish children, who, as has been seen, are cared for by a committee of their own. The work at the commencement was treated as an addition to the duties of the Thrift Committee, a position which it soon outgrew. It got, therefore, the benefit of an existing arrangement under which the names and addresses of children leaving school are furnished by the masters and mistresses of the schools with a view to the payment of visits to the homes in order to persuade young people to join juvenile friendly societies.

The school authorities, managers, masters and mistresses, have proved themselves sympathetic and helpful towards the new scheme. They demonstrate in this as in other matters the genuine interest which they take in the welfare of the children. One gentleman, in a responsible position, on the scheme being explained to him, was good enough to style it the missing link between the age of dependence in childhood and the age of self-support in manhood. The helpful attitude of the London County Council will be mentioned later on.

Having got the names and addresses of the children, a visitor, as the next step, is sent to the home of each child. The visitor discusses future prospects with the child and the parents, urges the advantages of industrial training, and invites the parents to apply to the committee. If the suggestions of the visitor be not successful, the facts are reported to the committee, and the influence of those who have previous knowledge of the family—the clergy, district visitors, and other local agencies—is invoked. Such persuasions take time; the visitations for the purpose may last for weeks. The case of no suitable child is abandoned until it is made clear that the parents will not consent to any beneficial suggestion, or that it is hopeless owing to the attitude of the child, or for any other reason, to make further efforts. It is found, moreover, that the children in increasing numbers are referred to the committee with the consent of the parent, by the school master, club manager, clergyman, or other person interested in the family. Those who have been placed, moreover, not unfrequently send their younger brothers, sisters, and friends. It is pleasant to add that parents are generally found to display much solicitude for the future of their children, and are, for the most part, willing that while they are learning a trade they should receive lower wages than are current in prospectless employments. Some parents, indeed, are ignorant, or neglectful, or grasping, but the attitude of parents on the whole is hopeful for the future of the undertaking. Some of the parents who are the most anxious for the training of their children and the most willing to make the necessary sacrifices are themselves unskilled men who have tasted in their own experience the bitter fruit of neglect in youth. The difficulty is sometimes with the child even more than the parent. A boy's horizon is often limited. He may fancy something to do with horses or any other job pursued by elder companions, especially if it be not too laborious, be well paid, and be done in the open air.

The parent on making application is asked to supply information about the child and about the family—the child's name, address, age, date of birth and school; the names, ages and occupations of other members of the family, with details of employers and earnings; the number of rooms occupied and the rent paid. These particulars are accepted on the statement of the parent. They are not, under ordinary circumstances, verified by enquiry unless money help be deemed advisable as will be explained subsequently. It is desirable to get as complete a picture as possible of the child's home surroundings, as home conditions have a strong bearing on industrial possibilities and prospects. Information is next sought at the school. The schoolmaster is asked to report on the child's standard, state of health, character and ability, and to make any suggestion which occurs to him as to a suitable occupation. Should the child seem specially delicate in health the opinion of his doctor or of the committee's hon. medical adviser is obtained. Such opinions are valuable in order that an occupation may be selected which is, as far as possible, harmless to the child's health. If the child be already in employment the parent is asked to give the necessary particulars. The whole of the information is entered on a special form; to this form are attached any other papers relating to the child. The file of papers is numbered and constitutes the case-papers to which all subsequent reports, letters and other documents about the child are added. Each case is indexed in a card index under the surname of the child.

The next stage, the advice given to the parent, is the most difficult in the whole work. In making the recommendation diverse considerations are borne in mind; the character and family circumstances no less than the abilities, tastes, and wishes of the child; the credit of the committee with employers, a matter of great importance; the prospect that the parents, who often have views of their own on wages and other things, will consent; the likelihood of an opening being available in the employment selected with an employer whom the committee is prepared to recommend. It is important that the blow should be struck while the iron is hot. If there be delay the parent or child may come under other influences in the choice of an employment, or the family may taste the sweets of higher wages than are forthcoming in good employments, or the opening known to the committee may be no longer available. The hon. secretary, therefore, or other worker who deals with the parent takes the responsibility, under ordinary circumstances, of making a recommendation without waiting for a meeting of the committee and reports to the committee what has been arranged.

A word may be added on the constitution and functions of the committee. An ideal committee is representative of all persons interested in the welfare of the children: in the home, the school, the office, and the workshop. The adhesion of the parents is important. The promotion of industrial training, like other influences on social habit, will not have its proper effect as an addition to the national life until the working people themselves are convinced of its necessity, and bring the public opinion of their own class to enforce it. The functions of the committee include supervision over policy, procedure, and expenditure. At its meeting every part of the work is discussed, and projected alterations and extensions are authorised. As regards each child on the books, the committee receives a report on the employment arranged or contemplated, gives directions in circumstances of difficulty, and decides whether and upon what terms further efforts are to be made on behalf of the child.

In approving the selection of a trade, the committee does not restrict its choice to any definite group of occupations. "Changes in industry," writes Miss H. W. Jevons, hon. secretary of the committee, in her paper on "Industrial Prospects for Boys and Girls" in the September (1906) number of the *Charity Organisation Review*, "have altered old meanings, and a skilled workman is now no longer a handicraftsman; he may be a machine-tending artisan. After all, the terms are only relative, and a skilled trade may best be distinguished from an unskilled by its requiring greater resourcefulness, general knowledge, and intelligence, as well as some training in the use of special processes and materials, the longer the training required the more skilled the work."

It is thought, therefore, that any occupation may be suitable which requires some training, which offers a prospect of continuous employment, and which fulfils the other desirable conditions. Nor is it deemed indispensable that the child should be bound by indenture. The children are placed as seems best, either with or without indenture, suiting the arrangement partly to the character and home

influences of the child, and partly to the custom of the employer and of the trade. Among openings in which indentures are not used preference is given to the employers who treat their boys and girls as if they were under articles, and give them opportunities of learning the trade if they be so minded.

When the parent has given a preliminary consent to the selection of a trade and of a particular opening in it, the committee undertake the duty of conducting the triangular negotiations between the parents, the employer and themselves. When satisfactory terms and conditions are agreed upon the child is taken on probation for a period, usually one month, before the arrangement is concluded. Employers, it is gratifying to state, almost without exception, prove themselves sympathetic and often express their satisfaction at the arrangements made for bringing them in touch with promising boys and girls. It is important that this good impression should be retained and deepened. On all grounds the good-will of employers is indispensable. It is advisable, therefore, that discrimination be used in introducing the particular child to the particular employer; the committee, moreover, while standing firm for the plain interests of the children, should avoid any thing in word or in deed which may be construed as undue interference or partiality in trade disputes, or other contentious matters.

In negotiating with the employers care is taken to stipulate that the children, whether to be bound by articles or not, shall be permitted to attend such technical classes of instruction as may be suitable. The due development of the artisan demands an admixture of theoretic and practical instruction. It is found, moreover, that those who profit most by technical instruction are those who are learning the practice of the trade in the workshop.

When a child is placed a further step of great importance remains to be taken: the committee appoints one of their members or other friend as guardian of the child. The duties of the guardian appear from a paper of suggestions drawn up by the committee in the following terms:—

"As 'Guardian' to a child you will be expected during the apprenticeship or period of learning the trade,

"1. To become on friendly terms with the parents and child, so that they will at once inform you if any trouble arises in the workshop, and to report it to the committee.

"2. To visit the child every month in order to ascertain that all is right.

"3. To report to the committee formally twice a year on the progress made by the child in your opinion and that of the parents; such reports to be given at the first committee meetings in May and November of each year. [N.B.—The committee will obtain a report from the employers.]

"4. To urge the child to attend such evening, continuation, or technical classes as seem good to you or are recommended by the committee.

"5. To encourage a child to join a juvenile friendly society during apprenticeship.

"6. To discharge such duties as arise out of the indentures, when such indentures are signed by you.

"N.B.—After the period of learning is over, the committee will be obliged if you will, from time to time, inform them of the further progress of the child in order that the after career may be ascertained."

The aftercare of the child through the guardian is important in order to secure a prosperous issue in the interests of both employer and employed. It adds, moreover, the personal touch which is as the breath of life to this as to every other form of charitable effort.

When it is proposed to apprentice the child a form of indenture which has been approved by the committee is suggested to the employer. Two special features in it may be noticed; the guardian is made a party to the indenture and is given the power of cancelling it on failure by either master or apprentice to fulfil its conditions. The master, moreover, covenants to permit the apprentice to attend technical classes of instruction without loss of wages.

When the usage of the trade, or the opening chosen, or the crippled condition of the child is such as to make it necessary to provide a premium, the parent is referred to the East London Apprenticeship Fund, which provides premiums on loan to suitable parents, without interest, repayable over a period of years by small weekly instalments. The secretary of the fund also keeps a list of openings and undertakes the preparation and completion of indentures. Apprenticeship committees working in a district not covered by the East London Apprenticeship Fund make, it is believed, similar loans. When the parent of the apprentice is unable owing to widowhood or other sufficient cause to repay the premium in this manner, the family are referred to the Charity Organisation Committee, which investigates the circumstances in the manner usual in applications for charitable relief, and makes a recommendation according to the

result of the inquiry. In approved cases the amount required is raised by application to endowed and other charities, to City companies, and to private persons. Such cases are not numerous. The funds available for them are considerable, and the committee in making such recommendations are gratified to aid in fulfilling the intentions of the original donors of many of the endowments.

As regards the numbers dealt with the committee's reports show that in the three years 1904-5-6 there passed through the books the names of 136, 138, and 142 children respectively, of whom there were satisfactorily placed 25, 26, and 40, or 19, 19, and 28 per cent. respectively. Of these 91 children, 39, viz., 24 girls and 15 boys, were bound as apprentices. The remaining 52, viz., 28 girls and 24 boys, were placed as learners or improvers without indentures. Out of the 39 apprentices, a premium was paid in 11 instances only, viz., 8 boys and 3 girls. Of these 11 premiums, 7 were provided by way of loan and 4 by gift. These figures are important as showing the large proportion of the work which may be carried on without the payment of premiums. In considering these figures it should be remembered that those who pass through the books are not, with some exceptions, selected children, but consist of all sorts and conditions of boys and girls as they leave school.

The 24 girls who were placed as apprentices were employed in 8 different trades; the 15 boy apprentices in 10 different trades. The 28 girls who were placed without indenture were employed in 15 different trades; the 24 boys similarly placed were engaged in 13 different trades. (Lists of these trades are given in an Appendix). Taking together those who were and those who were not bound as indentured apprentices, 52 girls were placed in 19 employments, and 39 boys were placed in 21 employments. Taking boys and girls together, 91 children were placed in 40 different trades. It is relevant to note the number and variety of the different employments.

The committee has not been long enough at work to be able to give useful particulars of the actual result of the training on the young people. The boys placed by the committee are still in *statu pupillari*. Some of the girls have served short terms of apprenticeship. The reports on them are on the whole satisfactory, and indicate improvement in conduct, manners, and health.

The account which has been given brings into strong relief the need of acquiring a varied stock of industrial information. It is desired to give each and every child who leaves the school, the opportunity of entering the trade suitable to his capacity. The committee are interested in all the children, and do not, with slight exceptions, aim at securing preferential treatment for any child. An important part, therefore, of the committee's work is concerned with the accumulation of facts, and the investigation of the conditions of industry. Such enquiries are necessary in order to appraise the several crafts and occupations according to their suitability in the present, and their prospects in the future.

It is necessary, as a second point, to obtain detailed information about the openings, which are from time to time available in the several trades. Such information will include the wages paid, the hours of work, workshop regulations and practices, the position of the employers, their treatment of the employed, and other points. The committee's workers visit the employers in order to gather the necessary particulars, and they take the opportunity of getting as much information as possible about the trade.

All this knowledge has to be gained, like other social information, by gradual accumulation. It is, at present, in a rudimentary state. In no part of the work is effort more needed than in the Intelligence Department It is clear, indeed, that the sufficient acquisition of information, in both its branches, is beyond the power of a local committee immersed in administrative details. The undertaking, therefore, is one which lends itself to a division of function between the local committees and a central association. To the local committees seems suitable the work of getting into touch with the necessary persons, of persuading parents, negotiating with employers, and placing and watching over the children. To a central association seems suitable the receipt, co-ordination, and supplementation of industrial information obtained by local committees so that the whole body of information may be available to each and all of them. The utility of such a division of function was proved by the experience supplied by the Bureau for the Employment of Women, who for three years from 1902 acted as such a central body to which were affiliated local committees dealing with girls. It became clear that the benefit ought to be extended to boys. In 1905, accordingly, with the cordial concurrence of the Central Bureau,

the Apprenticeship and Skilled Employment Association was formed in order to undertake the duties proper to the central body. Local committees dealing with boys and girls may become affiliated to the Association and obtain access thereby to information and more numerous openings of employment. The affiliated committees at present number 10.

It is time to pass on to the comments which the account suggests. The training of young people in a trade has uses other than the augmentation of earnings. It may be regarded as a continuance of their education; a drawing out of their capacities of mind and body, an opportunity for the inculcation of thrift, as a discipline and a means of growth in the traits which befit men and women. This aspect of the work should ever be borne in mind. It would not accord with the objects of the committee that a child should be instructed in a single process only, however high may be the reward of his dexterity. It is hoped through the scheme to provide a partial antidote to the modern tendency to reduce workpeople to the mental condition of animated machines.

The scheme is remedial in another way. Modern society is based on the free exchange of commodities and services. Thousands of men and women fail to secure sufficient maintenance owing to the insufficiency of that which they offer in exchange. They get little because they give little. They are unable or unwilling to do, or to do regularly and continuously, that which is useful to other people. The committee desire to equip the rising generation with an improved capacity of doing that which has a sufficient, regular, and continuous value in exchange. The labour of those who become skilled in supplying their neighbours' wants will add, in the words of Adam Smith, to the "common stock where every man may purchase whatever part of the produce of other men's talents he has occasion for." There is abundant scope for such increase in production. The home of each producer is a market for the yield of all producers. In thousands of English homes the standard of living is low; narrow incomes leave desires unsatisfied. A rise in purchasing power in these homes will cause an expansion of the market. It is relevant in this connection to call to mind the variety of trades in which the children were placed even in this small undertaking. The acquisition of fresh markets for British industry is in these days an object of solicitude. In the interest of markets travellers explore, diplomatists negotiate, statesmen annex, engineers build, taxpayers groan, soldiers bleed. These efforts command sympathy and approval. It must not, however, be forgotten that all the while at home, at the very doors, lies a great potential market in the unsatisfied desires of thousands of men and women, whose productive capacity, now uninstructed, falls far short of their capacity when instructed. The work of the committee may in one aspect be deemed an effort to create such a new market.

An increase in the productive power of the people, furthermore, is likely to prove remedial of the evils arising from lack of employment, of which much has been heard in recent years. These evils are of long standing and have deep roots. They grow out of untrustworthiness of personal character, the cyclic alternations of activity and slackness in trade, and modern conditions of industry, including an increasing subdivision of employment, and the growth of cities. The evils in question, moreover, have been aggravated by the dominance of a public opinion as to the responsibility of the community towards the workers, based on a misinterpretation of both social facts and social duty. Public men and the dispensers of voluntary benevolence conspire to undermine the poor man's self-reliance, and forestall the efforts on behalf of his family to which affection prompts him. The distressful symptoms, indeed, connected with lack of employment, do not come as a surprise to those who have watched the social drift. Anxiety has been long felt with regard to the upbringing of children, especially in cities. The influence of the home has waned, and the strongest of all educative forces has thereby lost much of its power. Parents come before magistrates, and assert with grave faces that children of nine years of age are beyond control. This impairment of parental authority over the children has coincided with the complete assumption by the State of responsibility for their education. Yet indiscipline among young people, known as hooliganism, survives.

When the children leave school, they are exposed to temptations arising out of the conditions of modern industry; their labour is forthwith worth a good price in employments which give poor promise for the future. An evil of the present day is the high demand for juvenile labour in occupations for which there is a relatively low demand for adult labour.

At the tail of a van, or by running errands, boys may earn from 7s. to 10s. a week, while

if they enter a good trade, they must be content with low wages, and possibly provide a premium. When the boy grows into a man, and asks for man's wages he is dismissed, as his labour at man's wages is not wanted. Another boy takes his place. Every year a number of young men are thus thrown on the labour market unable to make anything or to perform any services which will procure them a full week's work. The facility with which a young man can get two days' work a week at good daily wages is demoralising. Idleness impairs his aptitude; permanent work grows irksome; he loses even the ambition to improve his position. The manufacture of the unemployed thus proceeds apace. It is hoped that by means of this scheme this "rake's progress" will be checked at the commencement. Accurate statistics are not available from which may be inferred the degree of protection against lack of employment which the knowledge of a trade affords. Experience, however, shows that the great bulk of the applicants to relieving agencies are of the unskilled and casual class. It is to be inferred, therefore, that protection against acute distress is gained either by knowledge of a trade or by the higher standard of living in respect of thrift and mutual aid which marks the more skilled workman.

The difficulty is aggravated by the industrial position of London, which, to quote Mr. Ave's words in "Life and Labour in London," vol. ix., by Mr. Charles Booth, "has no staple industry. ...... She is a great purchasing market for those resident elsewhere ..... and holds a unique position in a variety of ways in which she acts as a centre of distribution for home, colonial, and foreign products." This statement is borne out by the census of 1901, which shows that of males over ten years of age, 16 per cent. of the whole is engaged in transport and the carrying of messages, and 8 per cent. of the whole is engaged in commercial occupations. It is these very industries which use a specially large amount of juvenile labour.

An increase in the proportionate number of young people instructed in productive industries will diminish the supply of unskilled labour, both adult and juvenile. As regards unskilled adults, supply has outstripped demand, and a reduction in supply tending to greater regularity in employment will be an unmixed boon. As regards juveniles, the diminution of supply may lead to the resumption of adult labour in these branches of industry and to some other favourable readjustment.

The difficulty with regard to girls, it may be noted, is less pressing than with regard to boys. Partly because good trades for girls—specially the wholesale and retail clothing industries—are common in London; partly because a young woman who marries leaves, for the most part, an opening to which a younger girl may succeed. The married man, on the contrary, needs to increase his earnings, if it be possible, on his marriage.

Mr. Aves refers to a second characteristic of London: "Although much of London labour is unskilled and degraded, much of it is of the greatest excellence, and is being constantly recruited from the best workmen that the country can produce." The parasitic character of London industry is illustrated with reference to the building trade, the largest of London trades, in a report of the London County Council Technical Education Board in 1898, which stated that "41 typical firms in various branches of the building trades, having 12,000 *employés*, had only 80 apprentices and 143 learners, instead of 1,600 which would have been the normal proportion. The London building trades are, in fact, recruited from the country." This statement is confirmed by the census of 1901, which shows in Table 32, that in the building trades in London the percentage of males between 15 and 20 is only 8 per cent., while the like proportion in conveyance is 16 per cent. Further inquiry is needed into the causes which serve to qualify country bred men, and to disqualify London bred men for craftsmanship of the best kind.

These thoughts about the training of young people as it promotes growth in faculty, an increased production and more widespread employment lead to a consideration of the method of training through which these results are likely to be attained. Among the ways in which a child may enter his trade two are of special importance. He may be placed as an apprentice under an indenture which binds both employer and employed; or he may be placed with the employer as a learner unbound by articles. Interesting as is the past history of apprenticeship, it affords small guidance in present difficulties. The apprentice of old time lived in the house of his master, who was responsible for his training in both morals and craftsmanship. The apprentice of the present day lives, with rare exceptions, at home as a member of his own family, and goes daily to work. Out apprenticeship has grown up under modern conditions

of industry. It differs widely from its ancient namesake. Unfavourable features, criticised in apprenticeship of the past, are not inherent in it. "The essence," writes Miss Bradby in the paper which has been mentioned, "of apprenticeship is that it is a contract enforceable at law, between the master on the one hand to teach or have taught, and the boy on the other hand to serve. All else is incidental. There may or may not be a preminm to pay. The duration of the apprenticeship may be anything from one year to seven. The boy may serve all his time with one master, or permission may be made for him to serve several in succession. He may have no wages, or very small ones, the first year, or he may start with from 6s. to 10s. a week. What is fixed is that he cannot, "while the relations created by the indenture subsist, "change his trade or employer without the consent of that employer, while his employer cannot get rid of him or have him taught less than thoroughly."

Apprenticeship, therefore, is a prolongation of the period during which the youth or maiden remains bound in *statu pupillari*. It tends, as an addition to its advantages as a training in industry, to counteract the premature blossoming forth of boys and girls as men and women.

The learner, on the other hand, enters his trade unbound by articles. He starts for the most part as an errand boy to a firm where a skilled trade is carried on. The sharpest of the boys may be put to the bench and have an opportunity of learning the trade, but those who have average abilities or have no interest with the firm are apt to remain uninstructed. A boy, moreover, even if he be put to the bench is liable to be dismissed or may never learn important branches of the trade, or may be tempted by the offer of higher wages elsewhere to start prematurely as an incompetent workman. It seems, therefore, that in the interests of the children the method of apprenticeship, modified to suit present requirements, is greatly to be preferred.

Much else, however, is in question. The application of machinery, superseding handwork, and the increasing subdivision of employment are obstacles to the fulfilment of the notion of learning the trade right through. Moreover, the changes of method in manufacture are rapid, and no process now requiring skill of hand is safe from the invasion of machinery. The organisation of industry, furthermore, by large companies with general manager, managers of departments, overseers, and foremen, is not always suitable to the training of apprentices. It is important to recognise that these conditions of industry flow like the tide; they will not stay in the interest of any. It is wise, therefore, to decline to prophesy on the methods which may hereafter prevail in the trainlng of the young.

One thing is certain. A supply of suitable labour is indispensable to industry. The managers of industry, therefore, will find a way of securing it. The responsibility rests with them. Their industrial life, under competition within and without the country, is at stake. Nor is it likely that employers who remain permanently in London will acquiesce in the dependence of London on country-bred workmen. A skilled employment committee, therefore, will gather information and watch developments, eagerly seizing all opportunities in the interests of the children which present themselves in the existing course of business. It is, however, of cardinal importance that charitable people should refuse to influence the method of training by the offer of money. Employers should not be bribed to take apprentices, nor should parents be bribed to bind their children as apprentices.

If an employer be offered such a premium as he would not get except from charitable sources, he will be discouraged from taking apprentices except when such a premium is paid. The consequence, therefore, of offering such premiums may be to diminish rather than to increase the number of apprentices. Similarly, if parents be offered an equivalent for the reduced wages of apprenticed children, they are discouraged in placing their children unless such an equivalent be forthcoming. They lose the opportunity of making a sacrifice for their children's welfare. It is not suggested that such premiums should not be paid where the child is crippled or under other disability, and needs special instruction, or when the parent is a widow and cannot repay a loan or forego the better wages which the payment of a premium may command. Further enquiry is needed into the number of apprentices who are being taken with and without premiums in the several trades.

The consideration of the payment of premiums leads to a reference to the report issued by the London County Council on the Apprenticeship Question in January, 1906. This report is prepared by the Apprenticeship Section of the Higher Education and Scholarship Sub-committee of the Education Committee. It treats the matter, as may be expected,

mainly from the educational point of view. It emphasises the lack of facilities for the training of London boys and the consequent dependence of London on the country for superior artisans; "the better positions go inevitably to the country-bred man with his all-round training"; though it is "not prepared to admit that the Londoner is, on the average, inherently inferior either in intelligence or in manual dexterity. His unfortunate situation is due to lack of opportunity for industrial training and not to any innate infirmity incapable of cure." It seems strange that the report does not proceed to inquire into the methods by which the country-bred workman got his all-round training. It ignores the possibilities of indentured apprenticeship, and recommends the creation of scholarships, carrying free tuition and in some cases a maintenance grant tenable at evening classes, day classes, and day trade schools. The proposal of maintenance grants is not made without some disquietude. "In the United States and Germany it is, we are informed, rare for public provision to be made for the maintenance of scholars. It is, we feel, not altogether a satisfactory feature that in this country there should be less disposition on the part of the parents to make sacrifices for their children's advancement, and less willingness on the part of young people to exert themselves than in other countries." Will it not be well to ascertain by experiment whether parents be willing to make the necessary sacrifices before exposing them to temptation by the offer of maintenance scholarships? The experience of the committee in this direction is encouraging. However this may be, the suggestions of the report seem to be aimed at the development of talent in clever boys rather than the offer to all children, as desired by the skilled employment committees, of the opportunities of increasing their productive power. The report is, nevertheless, a valuable document in the cause of industrial training. It reports adversely and most wisely on the suggestion that public funds should be used for the payment of premiums. Such a use of public money would impair the responsibility alike of employers, of parents, and of those who seek to befriend the children.

The report, in the second place, recommends that the London County Council, as the educational authority, should co-operate with apprenticeship and skilled employment committees; the paragraphs of the report deserve to be quoted *in extenso*:—

"But undoubtedly the most beneficial results would be obtained by bringing the elementary schools themselves into closer touch with the various apprenticeship agencies. In many of the poorer schools of London there are children, known to the head teachers, who require assistance in finding a suitable opening. Much good could be done by acquainting the head teachers with the resources of the neighbourhood. At the present time several have made it a part of their duty to assist the children, in the way of finding them employment, as they leave school. This excellent work should be encouraged. The head teachers, who appeared before us, agreed that they would gladly make use of apprenticeship societies or outside agencies if they were furnished with information. We suggest that these charities should be classified according to areas, and that the head teachers (senior departments) of all elementary schools within such area should be furnished with the corresponding particulars. In order that the Council may learn the result of this action, we suggest that the head teachers should be asked to report, in October of each year, what steps they have taken to disseminate the information among the scholars during the preceding year, and whether any children have been apprenticed in consequence. It might also be useful to supply the head teachers with handbills for exhibition, containing particulars for openings for boys and girls about to leave school. A communication should also be sent to the several charities asking them whether the Council might be allowed to submit to the governing bodies suitable candidates. We are further of opinion that the information regarding apprenticeships should be supplied to the managers of the public elementary schools, and that among the duties of managers of the L.C.C. schools, a prominent place should be given to the duty of inducing the children to enter skilled trades as they leave school."

The report, as a further point, lays stress on the utility, for the purposes of technical instruction, of evening classes, day classes, and trade schools. These various methods of combining theory and practice have their respective advantages in the training of young people, who differ in grades of skill and in prospects.

It may be useful to summarise the points on which further inquiry is desirable in the interest of the future work. Some of them have been mentioned.

1. The ascertainment with reference to as many trades as possible of (i.) the conditions obtaining in them as affecting the moral and industrial welfare of those who enter them, and (ii.) the prospects which they afford of satisfactory employment for adults.

2. The ascertainment of the industrial history

of the children who have left selected typical schools during the past few years.

3. The ascertainment of the conditions under which young people receive industrial training in employments in which (i.) instruction is haphazard, (ii.) indentures are used, (iii.) indentures are not used.

4. Inquiry into the proper function of means of instruction other than the workshop, *e.g.*, classes and day schools.

5. The extent to which premiums are actually paid, (i.) by parents, (ii.) by charitable funds.

6. The proportion of country-bred men in selected London good trades and the causes of their superiority.

These inquiries should be made in the interest of the bulk of the children, and, so far as possible, from all persons interested, both employers and workmen.

It is clear from the account which has been given that the scheme to improve the industrial training of the young is itself young. It enjoys the vigour of youth. It makes large demands upon those who undertake it in the conduct of the necessary investigations, in digesting ascertained facts, and in rightly interpreting experience. It invites support and personal help. It offers to those who are minded to take part in it a practical and productive field of work. It is, moreover, rooted in a sound economy and a just interpretation of social facts. It is not casual and fortuitous. It has arisen in order to supply proved needs. Economic independence is the joint product of a man's capacity and willingness to contribute what is wanted to the common stock. An increase in such productive aptitude is the main aim of the scheme. In fulfilling this purpose it allies itself with those qualities which are alike the cause and the effect of independence in economic position; with strength of character, industrious habits, forethought, and the play of family affection. The work, therefore, has a well-marked place in the calendar of social service, and claims the sympathy and aid of those who value the traits which befit the free members of an industrial community.

APPENDIX.

List of trades in which children were placed in 1904-5-6:—

Boys.

Apprentices.—(1) Wheelwright; (2) Printing; (3) Motorworks; (4) Mathematical instrument maker; (5) Surgical instrument maker; (6) Engineering; (7) Pattern-making; (8) Plumbing; (9) Tailoring; (10) Bookbinding.

Learners.—(1) Tea-packing; (2) Engineering; (3) Bookbinding; (4) Stable-boy; (5) Foundry; (6) Draughtsman; (7) Chemical works; (8) Librarian; (9) Hospital porter; (10) Errand-boy; (11) Cork trade; (12) Service; (13) Candied fruit.

Girls.

Apprentices.—(1) Dressmaking; (2) Millinery; (3) Upholstery; (4) Artificial flowers; (5) Embroidery; (6) Feather-curling; (7) Relief stamping; (8) Box-making.

Learners.—(1) Collar-making; (2) Dressmaking; (3) Mantle-making; (4) Tie-making; (5) Artificial flower making; (6) Blouse-making; (7) Trimming-making; (8) Machining; (9) Book-folding; (10) Upholstery; (11) Costume machinists; (12) Millinery; (13) Tailoring; (14) Wholesale clothing; (15) Ready-made clothing.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said it was nearly 100 years ago since the Statute of Apprenticeship was repealed by the Legislature, and a remedy for the questions with which that Statute dealt was still being sought for. For many years there were few things discussed more than the question of apprenticeship. As far back as the twelfth century legislation on the subject was passed, and the Statute of Elizabeth, which prevented any person engaging in work who had not been apprenticed for six years, was the most important condition of the training of the young workman. Adam Smith opposed it strongly, first, on the ground that seven years was far too long, and secondly, that it prevented, by the restriction of the number of apprentices, large numbers of persons becoming good workmen who would wish to do so but who were unable to obtain apprenticeships. There was no doubt that, although it tended to a good sound teaching of a limited number of workpeople, it was not satisfactory in other ways, and that it produced a large and vagrant class. Adam Smith thought it was possibly for the benefit of the master and also for the benefit of the apprentice, but that it was not for the benefit of the public, who, he considered, would gain greatly by having the conditions of labour free and untramelled. There was no doubt whatever that the increase of English industry which occurred subsequent to the repeal of the Statute, was largely helped by the greater flow of workpeople into the common industries of the country. He did not think people realised how necessary it was that there should be a thorough and complete training of the young person who became an apprentice. At the time of the abolition of the Statute,

there were all over the country charities for dealing with apprentices, especially in London. Under the conditions of public opinion and the actions of the Charity Commissioners, the great bulk of those charities had been utilised for the support of technical education. They had now, at the end of 100 years, to consider what was to take the place of apprenticeship and to do its work more efficiently. There were several apprenticeship charities still existent. He himself was a trustee of the Campden Charity at Kensington, which formerly spent very large sums on apprenticeship, and it was now spending annually about £300 to £350 in that direction. It apprenticed a number of children who were born in Kensington at premiums of from £15 to £30 in each case, and the result had been on the whole extremely satisfactory. There was a large number of trades in which it had been possible to apprentice children; and he could not help thinking that, in the revival of the apprenticeship system under a new form in connection, to a large extent, with the evening schools where technical education was given, the help of such money as still remained allotted to apprenticeship, amongst the charities of the country, would be very useful. He would conclude by mentioning one fact to show that the parents and the children took an interest in the matter. A short time ago, when he was sitting as a magistrate to hear cases for compulsory attendance of children, a widow and a boy of about thirteen came before him. The boy absolutely refused to attend school, and when asked the reason, the boy replied that he was not going to school any more, as he wanted to be sent to an industrial school. He pointed out to the boy, that being sent to an industrial school was a punishment; he would be under very strict discipline, and, to a certain extent, there would be a stigma against him, but the boy replied that if he remained as he was, he would never be taught a trade, whereas if he was sent to an industrial school he would be taught one.

Mr. H. V. TOYNBEE thought there was a very common impression in some quarters that apprenticeship was practically non-existent at the present time, that being the general drift of the argument in the report of the Education Committee of the London County Council, and various suggestions were made to take its place by which skilled trades could be taught. It was a question whether apprenticeship was so obsolete as was sometimes imagined, and, consequently, whether any other system could be devised by which a trade could be thoroughly taught. The Jewish Board of Guardians, when they desired to give the children who came before them a good industrial start in life, turned to the apprenticeship system, and in 1905 they apprenticed over 400 children, having up to that time under their care 1,000 boy and girl apprentices. The East London Apprenticeship Fund had apprenticed about 800 boys and girls, and if it had had a larger income would have apprenticed more. A committee in South London, connected with the Women's University Settlement, had apprenticed in quite a short time 150 boys and girls, and similar work was being carried on by apprenticeship committees throughout the whole of London. In the Admiralty dockyards, and in all the various departments of shipbuilding and engineering, the hands were trained by means of apprenticeship, plus compulsory attendance at technical classes. The same remark applied to the Great Western Railway carriage works at Swindon, and many other undertakings. In the printing and plumbing trades the dearth of skilled workmen became so acute that a joint movement was made by the masters and representatives of the trade unions to improve both the trades, and an apprenticeship board had been started in order to encourage it. As time went on it became increasingly easy to find openings for apprentices, and he thought he had shown that apprenticeship was still very largely in existence. The part that apprenticeship committees was playing was one of extreme importance, but up to the present time their work had not been sufficiently recognised. They acted as connecting links between the elementary schools on the one hand, and the employers of labour and various apprenticeship charities on the other. In his opinion the most important part of their work was the after-care of the apprentices, in seeing that the conditions laid down by the indentures were carried out. Of the various ways by which a skilled trade could be taught, he thought indentured apprenticeship, coupled with attendance at technical classes, was the most satisfactory. Without indentures he did not believe it was possible to secure, either that the child was thoroughly taught his trade, or that the master made provision for him to attend technical classes. His experience at Southwark had been that masters were ready to agree to a clause being inserted in the indentures by which a child was allowed to attend technical classes without any loss of wage. Two alternatives were generally suggested for the apprenticeship system, one being the part-time system and the other the system of trade schools. Under the former, the child spent a portion of its time in the workshop and the remainder in the technical school. He did not think that did away with the necessity for indentures, because without them the child might be made a drudge; there was no guarantee that the trade would be thoroughly taught, and the master might rely on the technical classes for the child learning the trade. He thought the part-time system might be a useful adjunct to the apprenticeship system, but he did not think it was a substitute for it. Excellent as the teaching was in the trade schools, he did not think it could be compared with that to be obtained in the workshop, where goods are made under ordinary trade conditions for profit. Admittance to trade schools also was by means of scholarships, for which there was keen competition, so that it was

only the sharpest children who had a chance of being successful. The schools did not cater for the mediocre boy or girl, and that class composed the largest number. To set up trade schools all over the country would be a costly matter, and that in itself ought to form a strong argument for not putting aside the apprenticeship system. With regard to the question of premiums, he thought the endowed charities, in London at any rate, might with very great advantage be amalgamated and administered under one Board, because it was found that in some parts very considerable charities existed and not many applications were made for them. There were other ways by which premiums could be secured. For instance, he did not see why the child should not be encouraged to save money whilst at school in a school savings bank, so that a sum of money should be available when he left for the purpose of his premium. There was no reason either why insurance should not be applied to the matter; in fact, he recently came across a woman who had deliberately insured each of her boys with the idea of obtaining a lump sum at the age of 14 with which to apprentice them. He suggested that the County Council, instead of exclusively encouraging trade schools, as they appeared to be doing, should also see whether they could not develop the apprenticeship system adapted to modern conditions.

Professor W. E. DALBY said that his knowledge of the subject was limited to the engineering branch. A friend of his, who owned a large manufacturing engineering business in London, made it a practice to ask the headmasters of the Board Schools in the district to keep him informed of the best boys that they had at the end of the year's course, in order that he might give them a chance in his works. That gentleman regularly recruited his works with apprentices of that class. He thought it would be a very great help to employers if, at the time the masters gave the educational qualifications of the boys, a note was placed on the card index giving particulars of their manners, which were very often deficient. In connection with the number of trades to which it was possible to apprentice youths, he very much regretted that in the engineering metal work trade much of the old handicraft skill was dying out. It was only necessary to look at the specimens of iron work in South Kensington Museum, such as armour, to appreciate the fact that it would be quite impossible to obtain such things in this country at the present time. That was largely due to the introduction of machinery. In the engineering trade especially, the effect of the introduction of labour-saving appliances had been to drive out the old-fashioned millwrights. Practically no millwrights, men who could go into a shop and turn their hands to every sort of work, were now being trained. The whole tendency of the present day was to specialise, and he was afraid it would be very difficult, especially in engineering, to avoid the apprentices being simply put to mind machines to start with. In an engineering shop nowadays it was almost a crime to use a file on anything, it being the rule that everything must come from the machine, and be put together without any handicraft skill at all. Anything which would tend to reintroduce a scheme which would increase the handicraft skill of the country would be of undoubted benefit. A large number of railway companies were realising that it was important to combine technical instruction with the ordinary apprenticeship but it was very rarely indentured apprenticeship, the boys being taken on, and called apprentices. At Crewe, Harwich, Swindon, Stratford, Doncaster, and all the large engineering centres, there was a tendency to allow the apprentices to go to the technical institutions connected with the works so many afternoons a week, their wages not being stopped. In Stratford, in particular, after attendance at the institution for two or three years, the directors selected the three best men, and paid their fees at some technical college for a course of two years. That had only been brought about in the last few years, and indicated a very great change of attitude on the part of the employers to apprentices. The author struck the right note when he said that the situation was in the hands of the employers. It was the employers to whom they must look to take the products of the technical colleges, and the question would never be solved until the employers as a body co-operated with the schools and chose the best boys, rather than trust to the haphazard applications that were made to them for such places as they had to fill by apprentices. The author had brought forward a general scheme for establishing a kind of employment bureau between the schools and the masters of different trades. That was felt to be a great need at Cambridge University a very few years ago, and an employment bureau had now been established there. When June came round every year, he found that one of his chief duties, in connection with the department over which he presided at the Central Technical College, was to deal with the appointments that students were trying to obtain by fitting the employer to the student. That showed the need for some central bureau or employment agency which would bring the two classes together; and if the Employers' Federation of London could be approached and brought into co-ordination with the schools and colleges, a great step in the right direction would have been taken.

Mr. MYERS said, having had thirty years' experience of apprentices in London, he desired to call attention to the difficulty which had been experienced during that time in finding suitable masters for the apprentices. The difficulty was to make apprenticeship popular with the employers. The Jewish Board had always had a very large number of boys anxious to be apprenticed, but had never been able to obtain

a good supply of masters. Two canvassers were permanently occupied in searching every part of London to find people who were willing to take the boys, and advertising was freely resorted to, but the difficulty still existed. The number of boys willing to be apprenticed was unlimited. The author probably knew that the Jewish Board had to stipulate that the lads should not be employed on Saturdays, and it might be thonght that that was the cause of the difficulty they laboured under. No doubt it was a difficulty, but he did not think it sufficiently accounted for the paucity of masters. If something could be done to popularise the idea with employers, many more indentures would be carried through. He thought the Jewish Society might be considered the pioneer in the revival of apprenticeship. It had at present under its care about 900 boys and girls. Curiously enough it found there was not so much difficulty in apprenticing the girls as the boys, an increasing difficulty being experienced in getting the boys apprenticed without the payment of a premium.

Mr. ISAAC MITCHELL, L.C.C., thought the subject could be approached from two points of view, the first of which had been dealt with by the last speaker. The Jewish organisation was on the look out, with the limited means at their disposal, for employers who would train boys and girls. That might be extended to some extent, but obviously it was impossible to include all the boys and girls that were being educated under that particular head, although it was certainly beneficial to take the boys and girls from their surroundings where they would not learn any special trade and, by the payment of premiums, train them up to a particular trade. But that was not the problem which had to be solved. It was necessary to devise some means whereby girls and boys would not be thrown upon the world when they were 14 or 15 years old, but would have their education continued after they left the elementary school, by imparting to them knowledge of some particular branch of industry. That was a big problem, which he was confident would never be solved by the revival of the old apprenticeship system. He believed the revival of the system was as dead as the Irish or the Scotch languages. there being just as little need for the training which was given under the old apprenticeship system as for the revival of those languages. Nowadays, in engineering shops, the apprentices did not learn the trade right through, because the employer did not want millwrights; he had so specialised his industry that he wanted a lad to acquire a knowledge of only one particular branch of the business, and therefore, from an economic point of view, he would not teach the lad anything but that one particular point. Working people at the present time wanted to produce as much wealth with as little labour as possible. Another phase of the problem was, that he did not think it would be possible to train lads in the bulk for any special industry without having a detrimental effect upon the people already in the trade. It had been said that there were practically no apprentices in the London building trade; but if all the lads who were working on the tails of vans had been apprenticed to the building trade, instead of 10 or 12 per cent. of those who followed the occupation being out of work the number would be 25 per cent. Something had to be done to maintain the men who followed a particular branch of industry in employment; and unless another side of the problem was tackled, he was confident that the evils of unemployment would be increased in particular trades if they were flooded with apprentices The only solution of the problem which he could see was in the direction foreshadowed by the report of the London County Council, whereby the children's education was continued beyond the age of 14 or 15 up to 21 years of age, the children not being placed upon the industrial market until they were fully equipped with a knowledge of certain branches of industry. If that were done, and the hours of labour also dealt with, there was a possibility that openings would be made in the direction the author of the paper desired.

Miss ADLER thought that one of the chief difficulties experienced was that of procuring really good teaching for the boys and girls as apprentices. It was of extreme value to have various methods of training going on side by side, and, therefore, she welcomed the formation of apprenticeship committees in different parts of London. At present there were not sufficient facts and figures to go upon; but in five or six years time, when the boys and girls, who had been apprenticed, were able to give their experiences, they would know what system should be adopted. With regard to the question of apprenticeship, and attendance at technical classes in the evening, the hours of labour for young people were so long, that it was impossible to hope they would be in a condition in the evening to deal with difficult points connected with mathematics or other branches of science which had some bearing on their training. If technical and workshop training was to go on side by side, every effort should be made to induce the employers to give time off during the week, so that undue stress should not be placed on the children. She thought Mr. Toynbee was a little unjust to the trade schools. They were a somewhat expensive development; but if in the result, they combated unemployment she thought no expense should be spared to benefit the economic conditions of the men and women of the future.

Mr. E. BRUCE said that he was not an advocate of the return to the old system of apprenticeship. In the old days, many of the masters simply took the boys for the sake of the premium they obtained with them, and the boys were very little better at the end of their apprenticeship for their so-called training. He had

seen something of the work done by the University Settlement in Nelson-square, and knew that the lads who were apprenticed grew up to be self-respecting young men, taking an interest in their work and lives. One of the most valuable features of the system was the visits that were paid to the employers and the parents for the purpose of seeing that the boys were actually taught their trades. There had always been a difficulty in poor districts in getting boys to go as apprentices, because the parents only considered the prospect of an immediate 7s. or 8s. a week, as against a smaller amount in the case of apprenticeship, and the parents argued that they could not afford to lose the money. He strongly objected to the suggestion that public money should be used for the payment of premiums, and thought that as a rule the work should be self-supporting. The parents should be made to feel that they owed some duty to their children. A suggestion had been made that the manners of the elementary schoolboy were not immaculate. The manners of the schoolboy were not learnt at school but at home; and although the elementary school teacher had a great influenee over his children, generally speaking he could not counteract the great influence of home life. With regard to the suggestion that the County Council should secure the co-operation of head teachers, he did not think they would object to doing the work, but he asked the members of the Education Committee not to give them any more forms to fill up if they could possibly help it.

Mr. C. A. BUCKMASTER thought there were one or two matters upon which his experience of work in connection with the technical branch of the Board of Education in different parts of the country might be of some use in regard to the problem in London. He had found that apprenticeship charities, were, as a rule, not properly applied. The difficulty of finding suitable employers, especially in small districts, was a very great one, and it often happened that money left for apprenticeship premiums was practically thrown away. An employer required assistance and would be glad to pay for it, whereas owing to the existence of these charities, he was paid for doing what he would otherwise be glad to pay for himself. When a state of affairs existed in which apprenticeship premiums were paid to a parent for the training of a boy in his own trade, he thought it it would be admitted that charity money was in very great danger of being misapplied. He agreed with Professor Dalby that, so far as he could ascertain, indenture apprenticeship was practically non-existent in the big engineering trades. The railway companies would not take indentured apprentices, but only premium apprentices. There were very few employers who would stand out against an offer of £100 or £200 with a premium apprentice, but for the rank and file of the workers there was practically no indentured apprenticeship, and certainly no agreement to teach every part of the trade. As a result, indentured apprenticeship tended more and more to throw the apprentice into employments in which there were only a very small number of persons, and with small masters rather than big employers. There was another point in which the relation of the workshop and the technical school was worth considering. One of the most important duties that the trade school could perform was to give the apprentice an insight into some of those branches of the trade which the subdivision of labour did not give him the opportunity of learning in the workshop. In the technical schools all over the country, employees in different trades very frequently came to learn one or two parts which they could merely see at a distance in the factory, and in that way the technical schools were able to give an all-round knowledge of the trade, which was so desirable if the bugbear of unemployment was to be reduced to its lowest level. The enormous difficulty of the problem was realised when one considered that even with the numbers given by the author, they were only dealing with the very fringe of the subject. Only a very small percentage of children were being taught a skilled trade; but the ultimate end they had in view was to secure the whole of the population of the country who had not been taught a trade of their own. Anybody acquainted with unemployed committees knew it was a common fact that 95 per cent. of the applicants were unskilled labourers, and until that was done away with it was possible to consider that the system of training persons was being properly carried out. As an historical fact, it might interest the author to know that no less than 40 years ago the apprentice charities of Battersea had in their indentures a clause requiring the employer to allow his apprentice to attend science or technical classes, for the purpose of improving himself in the theoretical branches of his trade.

Mr. ALFRED MILWARD said there appeared to be a general idea that the apprenticeship system was failing, but it had been very successful in the Poor-law Schools of St. Pancras. The Guardians of St Pancras apprenticed boys or girls, paying a small premium of £6, the first half being payable on the signing of the indentures, and the second at the end of the year, if everything was satisfactory. An allowance, in addition to the premium, of about £3 10s. was made for the purchase of an outfit. Most gratifying results had been obtained, in some instances the boys becoming so proficient in their trades that they had set up for themselves, and had taken apprentices from the same schools in which they were brought up. The boys who were placed out under the Poor-law system had the great advantage of being looked after by the Association for Befriending Boys. That society had reported upon 151 boys placed out by the guardians of St. Pancras, and in the majority of cases the results were satisfactory.

The boys had nearly 12 months training in the schools in the particular trade to which they were eventually apprenticed, and being residential schools they had the advantage of learning the elementary parts of their trade whilst they were at school. It was undoubtedly the fact that, in many cases, the Poor-law children had advantages superior to those possessed by the children of any of the ratepayers. Most of the apprenticeships were indoor apprenticeships, but in some cases outdoor apprenticeships had been arranged, the boys being placed with a family, and their earnings being supplemented for a short time by the Guardians.

Mr. PARSONS, in reply, said he particularly wished to refer to Mr. Mitchell's remarks, because it was most important that the leaders of the working classes should be in sympathy and harmony with the movement; in fact it would be impossible to carry it through unless that state of things was brought about. Mr. Mitchell seemed to fear that, if the movement largely increased, the prospects of the existing working-men would be injured. He had given a great deal of study to the subject, and sincerely believed that such an argument was a complete fallacy. Nothing could be better for the whole of the working-men of the country than that its productive capacity should be increased. Mr. Mitchell seemed to think that a large number of people would be produced who had all been brought up to the same trade, the illustration which had been used being that if a great many more boys were apprenticed to the building trade the per-centage of unemployed would be increased. It was important to show, as he had carefully done in the paper, that, from the necessities of the case, it was necessary to cover a very wide area of trades. For instance, in the small scheme with which he was connected, 91 children had been apprenticed to 40 different trades, so that it was quite clear there would be no danger of swamping any particular trade. The only way in which the children could be taken on was through the employer; he would not take them on unless he believed the undertaking would be a success. These facts seemed to constitute an automatic check on the undue invasion of any trade. He earnestly hoped that Mr. Mitchell and his friends would seriously consider the proposition he (the speaker) put forward, viz., that an increase in the productive power of the country would be of benefit to all.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Parsons for his interesting paper, said that in connection with the Campden charities of Kensington, 142 children had been apprenticed to 32 different trades, figures which supported the contention that the apprenticeship system which was adopted covered a large area of trades.

The resolution was carried unanimously, and the meeting terminated.

GOLD MINING IN ASIATIC COUNTRIES.

Of the total gold yield of India, the Kolar Field in Mysore furnishes 99 per cent.; the only other producer from lode mining, outside of this small area, is the Hutti mine at Hyderabad, owned by the State. The output of the gold-producing States in 1905 was, according to the Geological Survey of India, as follows: —Mysore, £2,363,457; Hyderabad, £50,060; Burma, £2,419; Punjab, £703; Bombay, £320; and the United Provinces, £7; total, £2,416,966, as compared with £2,366,079 in 1904. The total yield of the Kolar Field in 1905 was 627,700 ounces of bullion (564,930 fine ounces), an increase of 4,012 ounces over 1904. The five leading mines together furnishing 98 per cent. of the field's output are the Champion Reef, Mysore, Ooregum, Nundydroog, and Balaghal, all of which are of importance; and, in addition, there are the Mysore West and Mysore Wynaad mines, which showed a good return in 1905. The Champion Reef, according to a report in "The Mineral Industry in the United States and other Countries," finds itself in the unaccustomed position of having to combat with poor zones of ore. The mines in the Kolar goldfield have repeatedly had to go through this ordeal. The Mysore mine had this experience at a very early period of its history, but quickly recovered. On the other hand, the Coromandel has spent many years in exploring for paying ore bodies. Ooregum and Nundydroog passed successfully through the trying time at about the middle of their present career. The Champion Reef mine, during the year ended September 30th, 1905, crushed 215,167 tons of ore, an increase of 33,219 tons over the preceding year. The year's output of bullion (216,802 ounces) was obtained thus:—188,596 ounces from the batteries, 2,617 ounces from No. 2 mill (now dismantled), and 25,589 ounces from the cyanide plant. The cyanide treatment is being curtailed; 177,000 tons of sand were cyanided in 1905. The employment of electric power secured from a number of independent generating stations has reduced the mining and milling costs by 4s. 4d. per ton, these two expenses having totalled £1 3s. 3d. per ton milled in 1905. The average yield is said to have declined from 1 ounce to 0·87 ounce per ton, which was to be expected in the increased tonnage milled. The records of the Geological Survey of India call attention to the Hutti mine, in the Nizam of Hyderabad's dominions, as still continueing to give good results, the output since the mine began to produce gold, in March, 1903, having been as follows:—1903, £14,505; 1904, £40,624; and 1905, £50,060. Another mine in the neighbourhood of Topaldodi has been opened, but it has not yet given any returns. In Burma, prospecting is still going on in the Chindwin river, and preparations have been made for starting active dredging operations on the Namma river in the Northern Shan States. The gold obtained by dredging in the Irrawaddi, in the Myitkyina district,

increased from 216 ounces in 1904 to 620 ounces in 1905, a second dredger having been got to work in the latter year. Only one of the Dharwar mines has so far given any results. In 1905 as compared with 1904, there was a decrease in the production of gold in the United Provinces and the Punjab, where the industry is entirely confined to native gold washing, said to be due to the light rains of 1905. In Kashmir also the production fell off greatly, from about 26 ounces in 1904 to only 10 ounces in 1905. The gold is derived from terraces in the Indus Valley in Kargil and Skardu. The Chota Nagpur gold washing is mainly confined to the valleys of the Karkari and Suvarnarekha rivers. The number of persons engaged in the industries fluctuates considerably as the people do not depend entirely upon it for a livelihood. In Manbhum the number employed was 255, and in Singhbum 154. In Corea, English, Japanese and American companies are engaged in gold mining. The largest of these is the Oriental Consolidated Mining Company of New York. This company owns six mines, five stamp mills and three cyanide plants, and leases three other mines. During the year ended June 30th, 1905, the company mined (including 2,826 tons of tribute ore) 257,647 tons of ore. This ore yielded in bullion and from sulphurets £202,000. Milling of the above output cost 2s. 4d. per ton, in which the cost of cordwood alone came to 1s. per ton. The five mills comprise 200 stamps; they ran for 320 days in the year and crushed four tons per stamp per day. The cyanide plants treated 32,556 tons of sulphurets, extracting 75·8 per cent of their gold, discharging tailing worth 3s. 3d. per ton. The cyanide treatment cost 5s. per ton handled, the cost of cyanide alone coming to about 1s. 10d. per ton. Ore reserves at the company's mines on June 30th, 1905, were estimated at 1,068,447 tons, a diminution of 23,355 tons during the year, occasioned entirely by a lack of labour. The Corean Government has been requested by the Japanese to grant permission to Baron Shibusawa and another Japanese to work the gold mine at Hamehung, in the province of Hamgyongdo. In Japan the gold mining industry is fostered by the Government, which itself works the recently discovered veins in the Iwate field. The chief placer deposits are in the Esashi district, Hokkaido. The principal vein mining centres are in the Echigo, Satsumo and Iwate districts. The chief mines are the following:—Innai, Kosaka, Sado, Hashidate, Tase and Kanagase, Kuratani, Taio, Hazami, Serigano, Okuchi, Ushio and Yamagano. The greatest output is obtained from the Kosaka, Sado, Yamagano, Ushio, and Tase and Kanagase mines. The value of the fine gold produced in Japan in 1903, the latest year for which the data are available, was £428,058, exclusive of Formosa. In the Malay States, the results of gold mining during 1904 do not appear to have been brilliant. The quantity obtained from crushings was 12,625 ounces from 54,961 tons in Pahang, and 2,189 ounces from 3,438 tons in Negri Sembilan. In addition, 146 ounces were obtained from alluvial washings and 2,115 tons of tailings by the cyanide process.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in November, 1906 :—

New Charts.—3613 - The World:—Mean lines of equal vertical force, 1907. 3564 - Scotland, west coast : - Loch Kishorn and the approaches to loch Carron. 1448 — Spain, south coast : — Acebuche point to Chullera point, including Gibraltar bay. Plan : — Algeciras roads. 3609 — Sardinia, north-east coast : — Port Terranova. 3583—Newfoundland : —Bay of Exploits, sheet V. 3610—Magellan strait : —Willes, Harriss, and Fox bays. 3611—Plans on the south coast of Sumatra : — Zutphen islands; Kiluang bay. 992—Japan :—Akkeshi wan. 3602—Anchorages in Yezo island :—Mombetsu anchorage; Mori roads.

New Plans and Plans added.—98—Plans on the south coast of Cuba. Plan added : — Puerto Francés. 1364 – Africa, west coast, cape Mesurado to Baffu bay. New plan :—Junk bay. 71—Bay of Bengal, Madras to Calimere point. New plan :—Pondicherri anchorage. 1495—Japan :—Aburatani bay to Ando zaki. Plans added :—Shichirui ura ; Yunotsu ura ; Yesaki ko. 2198—Harbours and anchorages on the north coast of Nipon. Plans added :—Yezumi ura ; Sagi ura. 3003—Japan :—Ando zaki to Otose zaki, including Sado island. New plans : — Niigata ko ; Ogi ko. Plans added :—Tsukumo wan ; Yebisu ko ; Naoyetsu ko. 3131—Anchorages in New Hebrides islands. Plan added :—Narovorovo.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners :—2390 — Scotland, west coast :—East and west lochs Roag. 2729—Ireland, west coast :—Sligo and Ballysadare harbours. 2210—Black sea, Plans in. 3206—Antartic ocean, Sheet VIII. 566—Iceland, eastern portion. 2980—Iceland :—Storksnaes to Portland. 2343—San Domingo :—Samana bay. 1982*b*—South America, east coast : —River Paranà, Sheet II. 516—Mexico, south-west coast :—Mangrove bluff to cape Corrientes. 3313—Alaska : — Yakutat bay. 654—Alaska :—Bering strait. 1363—Africa, west coast:—Sherbro island to cape Mesurado. 833—Bay of Bengal :—Rangoon river and approaches. 1180—China, east coast :— Approaches to Hong Kong. 1466—China, east coast :—Hong Kong. Fotaumun pass. 2412. Japan :—Amoy to Nagasaki. 2924—Australia, east coast :—Cape Grafton to Hope islands.

These charts are issued by Mr. J. D. Potter, 145, Minories.

HOME INDUSTRIES.

The Port of London.—In June, 1900, a Royal Commission was appointed to inquire into the subject of the administration of the Port of London. In June, 1902, the Royal Commission submitted their report. Paragraph 253 runs as follows:—"It has, in our opinion, been proved that the Port of London is in danger of losing part of its existing trade, and certainly part of the trade which might otherwise come to it, by reason of the river channels and docks being inadequate to meet the increased and increasing requirements of modern commerce." And the concluding paragraph of the report has the following:—"The Port has for a time failed to keep pace with the developments of modern population and commerce, and has shown signs of losing the position relating to other ports, British and foreign, which it has held for so long." The report recommended various drastic changes and the expenditure of some £7,000,000; £2,500,000 estimated to be necessary for permanent improvement of the river, and £4,500,000 for the improvement and extension of the docks. The additional capital required to meet these charges and the necessary cost of maintenance and working expenses might be, in the opinion of the Royal Commission, provided, so far as the £2,500,000 was concerned, by the municipal authorities, the Port Authority finding the £4,500,000 by the issue of Port stock. Nearly five years have passed since these recommendations were made, but little has been done towards giving them effect. The late Government intended to do something, but did nothing; and the present Government has given no indication of its intentions. Meantime the years pass, and the need for improving the river channels aud the dock accommodation becomes more imperative. It cannot (if Liverpool is excepted) be said that absolutely or relatively the Port of London has in the years that have passed since the Royal Commission reported "shown signs of losing its position relatively to other (British) ports." Taking the four leading ports the figures are as below:—

Year.	Imports. Tons.	Exports. Tons.
	London.	
1900	9,580,864	7,119,673
1904	10,788,212	7,850,947
	Liverpool.	
1900	6,001,563	5,666,145
1904	7,986,584	6,730,206
	Tyne Ports.	
1900	4,871,427	6,407,089
1904	4,805,067	6,589,972
	Cardiff.	
1900	5,132,523	7,636,717
1904	4,795,406	8,324,066

The tonnage entering the Port of London to-day, is much larger than when the Royal Commission reported. The growth of London itself as a market for goods tends to increase the trade of its port, but the competition of the newer ports, British and foreign, grows keener, and if the Port of London is to continue to hold its own, some such improvements as those indicated by the Royal Commission must be effected within the next half a dozen years.

The Dock Companies and the Port.—The delay in undertaking the improvements suggested by the Royal Commission has been mainly due to uncertainty as to what the Government propose to do, but this delay, and the pressing need for improving the river channels and dock accommodation, have induced the dock companies to move to obtain a remedy, and the London and India Docks Company will promote a Bill in the coming Session of Parliament. It deals principally with the deficiency of dock accommodation, and the financial difficulty. One clause would enable the company to impose dues upon all goods imported from beyond the seas. Under the scheme of the Bill it would be necessary to raise £350,000 a year, and that would require an average of about 9d. per ton on all foreign goods entering the port. Another clause would enable the company to collect from barges entering the docks, 3s. 6d. for each barge of under 100 tons, and 5s. on each barge in excess of that tonnage. In this matter of barges, the Port of London is under distinct disadvantages as compared with other ports. The dock companies may not charge for the use of their docks as such. It is estimated that 80 per cent. of the cargo loaded into ships in the docks is brought alongside in lighters, and 75 per cent. of the cargo discharged in the docks is taken away in the same manner by the consignees. The statutory exemptions in the Dock Acts secure to lighters the free use of the waters of the docks, and so the companies obtain no revenue from dues on goods so brought in and taken out. The Royal Commission recommended that the Port Authority should have power to levy a licensing fee, according to tonnage and description, upon all barges using the port, and plying in the river, or in the docks, or in both. A meeting of London shipowners was held a few days ago to consider the Bill referred to above, and a resolution was passed calling the attention of the Government "to the fact that nearly seven years have now elapsed since the Royal Commission to inquire into the Port of London question was appointed; that the long delay in legislating upon the subject is causing serious injury to every interest concerned in the Port of London," and expressing the hope that, subject to modifications, "His Majesty's Government will use its influence to secure the passing" of the Bill under discussion "during the Parliamentary session of the present year." It is already evident that the clauses relating to the dues will meet with strenuous opposition, but whatever the fate of this particular Bill, it is to be hoped that the improvement of the Port will not be much longer neglected. Where all agree as to the need, there should be no insuperable difficulty in arriving at agreement as to the means.

Insurance.—1906 will be long remembered by the managers of insurance companies for the unprece-

dented losses incurred by them owing to the fire at San Francisco. Hitherto no British fire office had been required to pay more than two-thirds of a million sterling as the result of any one fire, and only one office, the London, Liverpool, and Globe, which in 1871 was the greatest sufferer from the Chicago fire, had reached these figures. But the San Francisco fire meant the loss of £1,000,000 to several of the British offices, whose aggregate losses exceeded £10,000,000. The financial strength of the British offices was demonstrated by the way they met their San Francisco engagements. Only one, a comparatively small office, found it necessary to make a call on its proprietors; some met their losses entirely out of balances carried forward in their profit and loss accounts, and the rest found their other reserves ample without calling upon their proprietors. Without exception the British offices concerned met their obligations promptly and in a generous spirit, and it can hardly be doubted that their business in America will show considerable expansion, unless, indeed, Congress accepts the Bill under which it is proposed to levy a tax of 5 per cent. of the gross premiums received in the United States by all foreign insurance companies doing business in that country, which is hardly likely. Apart from San Francisco, the business of the British fire offices in 1906 was good. At Valparaiso they were protected against loss, as is the case at Jamaica; and it is to be assumed that in the United States the new policies will protect them against loss, not only directly but indirectly, caused by earthquake.

The Shipbuilding Output.—The figures for the past year are now available, and show a large increase in the output of new ships as compared with 1905. In that year the tonnage amounted to 1,805,968 tons, as compared 2,002,571 tons in 1906. The Clyde heads the list with 598,846 tons, as against 539,850 tons in 1905, the Tyne coming next with 411,569 tons, as against 338,645 tons in 1905. Then follow the Wear, with 334,572 tons, and the Tees and Hartlepool with 292,344 tons. Taking the three kingdoms, England heads the list with 1,193,881 tons, as against 1,073,309 tons in 1905. Scotland is second, with 658,139 tons, as against 587,932 in 1905, Ireland coming far behind with 149,860 tons, as against 144,727 in the previous year. 1906 was notable not only for its record output but for the launch of the largest merchantman ever put into the water, the Cunard steamer *Lusitania*, of 33,000 tons, built by Messrs. John Brown and Co., Clyde Bank. The activity of the shipyards in 1906 largely accounts for the domestic demand of the year for iron and steel of all sorts.

The State of Trade.—Reference was made in these Notes last week to the Board of Trade returns with their record figures showing an increase of 43,000,000, or 7 per cent. in imports, and of 53,000,000, or 13 per cent. in exports, and it was pointed out that the increase in quantities was not so pronounced as would appear from the mere values, yet they were none the less satisfactory. In his usual half-yearly review the Chairman of the Union of London and Smith's Bank emphasised this point, and went on to remark that high prices of raw material affected the manufacturers' profits considerably, and must tend to decrease their output, so that the profit derived from this large volume of trade may not have increased in proportion. There can, however, be no doubt that 1906 was an exceptionally good year for the working-classes. Whereas the prices of raw material, especially minerals, rose considerably, employment improved, and the prices of articles of food were either less or rose only very slightly. The prospects for the coming year too are very hopeful. Sir Felix Schuster says that from all the centres in which his bank is represented reports come full of promise as regards the future, and this is especially the case in the north. There is general and remarkable activity. In some places there is scarcity of labour where work is going on day and night, and so far as the export trade is concerned there is great activity. It is less with the home trade but it is hoped that this too will improve. But it is becoming every year more apparent that only those who are up-to-date and alert can succeed. Even farmers are doing better. There is only one considerable trade that remains depressed—the building trade, which is slack or stagnant, slackness which may be attributed largely to over building a few years ago, and probably in some measure to the effect on the smaller tradespeople of high municipal rates, and a heavy income tax.

The Home Demand.—The weak point in the industrial outlook which on its face seems so promising is the state of the home market. Trade is good, but it is the export trade, not, as in the case of our great rivals, Germany and the United States, the home trade. In those countries the enormous home demand is occupying practically the whole attention of manufacturers, whereas here, if it is not stagnant, the improvement is slight. The demands of the American and German home markets have helped British manufacturers by relieving them from foreign competition. They have indeed been supplying our most formidable competitors with materials, but what when supply has overtaken demand abroad? Note the sharp break in pig-iron warrants.

OBITUARY.

ALLAN WYON.—Mr. Wyon, who held the office of Engraver of H.M.'s Seals from 1884 to 1901, died at his residence at Hampstead on January 25th. He was born on July 4, 1843, and educated at King's College School, London. He was the son of Mr. Benjamin Wyon, and he belonged to a family of medallists. An ancestor of his came over from Germany as Court goldsmith to George I. Among

other works he executed the Royal Jubilee Medal of 1887, Episcopal Seals for the Archbishops of Canterbury and York, the Great Seal of Ireland in 1890, and the Seal for the Secretary for Scotland in 1889. He was elected a member of the Society of Arts in 1892, and on November 29, 1899, he read a paper on "The Great Seals of England." For many years the Society's medals were produced by the Wyons. Amongst others, the die for the Albert Medal, with the bust of H.R.H. the Prince Consort, was the work of his firm.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

FEBRUARY 6.—"The Principles and Practice of Insurance, and their modern Developments." By THOMAS EMLEY YOUNG, B.A., Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association. H. J. MACKINDER, M.A., Principal of the London School of Economics, will preside.

FEBRUARY 13.—"Motor Omnibuses." By LORD MONTAGU OF BEAULIEU.

FEBRUARY 20.—"Cold Storage and Food Supply." By HAL WILLIAMS. SIR EDWARD MONTAGUE NELSON, K.C.M.G., will preside.

FEBRUARY 27.—

MARCH 6.—"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S.

MARCH 13.—"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc.

Dates to be hereafter announced:—

"Smoke Prevention in Factories." By JOHN B. C. KERSHAW, F.I.C.

"The Underground Water Supply of the Thames Basin." By CLAYTON BEADLE.

"Engraving and Photogravure." By. J. CRAIG ANNAN.

"Modern Typewriters and Accessories." By ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts.

"Hungarian Arts, Home Home Industries and Commerce." By LOUIS FELBERMAN.

"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon.

"Aerial Navigation." By MAJOR B. F. S. BADEN-POWELL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 14.—"The Practical Side of Famine in India." By SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces. THE RIGHT HON. LORD CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. This paper hus been unavoidably postponed from February 19th.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

LECTURE II.—FEBRUARY 4.—*Lode Mining.*—The term "reef" used both for ore and "country" rock—The chief types of gold-bearing lodes—The importance of ore genesis in reference to mine development—The chief gold fields of the world and their structures—The Rand and its banket.

LECTURE III.—FEBRUARY 11.—*Gold Production.*—The crushing of the ore; the stamp mill—The extraction of gold by amalgamation; smelting; chlorination and cyanidation—Reforms in consequence of the tube mill and the filter press—Tube mill *versus* pan—Proposed abolition of the stamp battery—The depth of ores; surface and secondary enrichment—Mining costs and gold mining organization.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

PROF. HERBERT JACKSON, F.I.C., F.C.S, "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 4...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. John Walter Gregory, "Gold Mining and Gold Production." (Lecture II.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Inaugural Address by the President, Mr. Richard St. George Moore.

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Messrs. P. Schidrowitz and F. Kaye, "The Chemical Composition of some Motor Tyre Rubbers." 2. "The Composition of some New Crude Rubbers."

British Architects, 9, Conduit-street, W., 8 p.m. President's Address to Students.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Mr. Martin L. Rouse, "The Bible Pedigree of the Nations."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Harry de Windt, "Through Savage Europe."

TUESDAY, FEB. 5...Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. C. Seward, "Survivals from the Past in the Plant World." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

Designers, in the Galleries of the Royal Society of British Artists, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. J. D. Craw, "Purposes in Colour Decoration."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Colonel R. E. B. Crompton, "Modern Motor-vehicles."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, FEB. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Thomas Emley Young, "The Principles and Practice of Insurance, and their Modern Developments."

Geographical, Burlington-house, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Col. W. G. Macpherson, "The Role of the Red Cross Societies in Peace and War."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Mr. C. E. Keyser, "A Day's Excursion among the Churches of South-east Norfolk."

Obstetrical, 20, Hanover-square, W., 8 p.m. Annual Meeting.

African, Criterion Restaurant, Piccadilly, W., 9 p.m. Mr. Leslie Probyn, "Sierra Leone."

THURSDAY, FEB. 7...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. Otto Stapf, "New Plants from Malaya." 2. Mr. F. Chapman, "Tertiary Foraminifera of Victoria.—The Balcombian Deposits of Port Phillip."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. H. J. S. Sand, "The Rapid Electroanalytical Deposition and Separation of Metals. Part I.—The Metals of the Silver and Copper Groups and Zinc." 2. Messrs. G. Barger and F. H. Carr, "The Alkaloids of Ergot." 3. Messrs. G. T. Morgan and F. M. G. Micklethwait, "Influence of Substitution on the Formation of Diazo Amines and Amino Azo-compounds. Part VI.—The Partially Methylated 4:6-diamino-m-xylenes." 4. Mr. F. Tutin, (*a*) "The Reduction of Hydroxylaminodihydroumbelluloneoxime"; (*b*) "The Constitution of Umbellulone. Part II.—The Reduction of Umbellulonic Acid." 5. Messrs. R. H. Pickard and W. Oswald, "Studies on Optically Active Carbimides. Part V.—The Aryl Esters and the Amides of 1-menthylcarbamic Acid." 6. Messrs. A. G. Perkin and W. P. Bloxam, "Some Constituents of Natural Indigo." Part I. 7. Mr. A. G. Perkin, "The Occurrence of Isatin in some samples of Java Indigo." 8. Messrs. W. N. Hartley and E. P. Hedley, (*a*) "The Absorption Spectra of Benzoic Acid; the Benzoates and Benzamide." (*b*) "The Absorption Spectra of Phthalic Isophthalic and Terephthalic Acids. Phthalic Anhydride and Phthalimide." 9. Messrs. H. Henstock and C. H. G. Sprankling, "$\alpha\alpha\gamma$ Trimethyl-and $\alpha\alpha\gamma\gamma$ Tetramethyl-tricarballylic Acids, and $\alpha\Delta$ dimethylbutane $\alpha\beta\Delta$ tricarboxylic acid." 10. Professor J. F. Thorpe, "A Reaction of Certain Colouring Matters of the Oxazine Series."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Prof. W. W. F. Pullen, "Some Forms of Dynamometers."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. Clifford C. Paterson, Discussion on Paper, "Investigation on Light Standards and the Present Condition of the High Voltage Glow Lamp." 2. Messrs. H. F. Haworth, T. H. Matthewman, and D. H. Ogley, "Comparative Life Tests on Carbon, Nernst, and Tantalum Incandescent Lamps using Alternating Currents."

Junior Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m.

London Institution, Finsbury-circus, E.C., 6 p.m., Dr. C. W. Pearce, "The Lives and Music of Henry Smart and Edward J. Hopkins."

Royal Institution, Albemarle-street, W., 3 p.m. Major Percy Macmahon, "Standards of Weights and Measures." (Lecture II.)

FRIDAY, FEB. 8...Royal Institution, Albemarle-street, W., 9 p.m. Prof. J. Gollancz, "Old English Poetry."

Civil Engineers, 25, Great George-street, S.W. 8 p.m. (Students' Meeting.) Mr. Claude Pain, "The Reconstruction of a Swing-bridge on the Southwold Railway."

Astronomical, Burlington-house, W., 8 p.m.

Geologists' Association, University College, W.C., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Royal College of Science, South Kensington, 8 p.m. Annual Meeting.

SATURDAY, FEB. 9...Royal Institution, Albemarle-street, W., 3 p.m. Rev. W. Barry, "Papal Deposing Power." (Lecture II.)

PANAMA CANAL.—Monsieur Bunau Varilla asks that following corrections may be made in his paper and discussion, printed in the last number of the *Journal*:—Page 250, col. 1, ll. 48-49, *for* "one quarter soft rock, one quarter hard rock, and one half earth," *read* "one half soft rock, one quarter hard rock, and one quarter earth." Page 274, col. 2, the prices of one shilling and ninepence a yard given by Mr. Quellenec and Mr. Hunter respectively, apply to the operation of making the excavations dredgable by the Lobnitz process, and the cost of dredging must be added to obtain the total cost of excavation.

Journal of the Society of Arts.

No. 2,829. VOL. LV.

FRIDAY, FEBRUARY 8, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 11, 8 p.m. (Cantor Lecture.) PROFESSOR JOHN WALTER GREGORY, D.SC., F.R.S., "Gold Mining and Gold Production." (Lecture III.)

WEDNESDAY, FEBRUARY 13, 8 p.m. (Ordinary Meeting.) LORD MONTAGU OF BEAULIEU, "Motor Omnibuses."

THURSDAY, FEBRUARY 14, 4.30 p.m. (Indian Section.) SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., "The Practical Side of Famine in India."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

Professor JOHN WALTER GREGORY, D.Sc., F.R.S., delivered the second lecture of his course on "Gold Mining and Gold Production" on Monday evening, February 4th, the particular subject being Lode Mining. Before treating of the chief types of gold bearing lodes the lecturer drew attention to the confusion caused by the use of the term "reef" for both ore and "country" rock. He then dealt with the importance of ore genesis in reference to mine development; the chief gold fields of the world and their structures, concluding with an account of the Rand and its banket.

The lectures will be published in the *Journal* during the summer recess.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, January 24; SIR WILLIAM LEE-WARNER, K.C.S.I., Vice-President of the Society, in the chair.

In the absence of the author, the paper was read by H. M. BIRDWOOD, C.S.I., M.A., LL.D.

THE BHILS OF WESTERN INDIA.

By Captain E. Barnes
(Indian Army).

The Bhils are an animistic race, inhabiting the wild and hilly tracts of Western India, which stretch from Udaipur in Rajputana southwards across the Vindhya and Satpura mountains to the plains of Nimar and Khandesh, and from the borders of Gujerat eastwards to the rich Malwa plateau. According to the Census of 1901, their number may be put at 1,200,000*, divided principally among the British districts of Khandesh and the Panch Mahals in the Bombay Presidency; the Native States of Indore, Gwalior, Dhar, Jhabua, Rutlam, Sailana, Ali Rajpur, Barwani, and Jobat, in the Central Indian Agency.

Origin of the Race.

As regards the origin of the race, modern writers hold them to be, equally with other animistic tribes of India, a relic of the aboriginal or Dravidian population; they themselves claim descent from Mahadeo, or one of his numerous incarnations, and the Vedic tradition claims for them a purely Aryan origin. One of their own traditions relates how Mahadeo, having come down to earth, lost his way in the dense forests, and while wandering therein met a maiden of great beauty, of whom he became enamoured and by whom he had a large family. One of the sons (the ancestor of the Bhils), distinguished from his early youth by his ugliness, the dark colour of his skin, and the evil habits of his life, crowned his career in his father's house by killing the sacred cow. For this offence he was exiled from the fertile countries of the plains to dwell for ever in the hilly forest tracks —a true Ishmaelite—to live by the sword in perpetual enmity with his more fortunate brethren.

The Vedic tradition, which I may briefly quote from the Vishnu-Purana,† after detailing the ancestry of Vena, who, it is stated, inherited the evil propensities of his maternal grandfather, observes that when "he was inaugurated, by the Rishis, monarch of the earth, he caused it to be everywhere proclaimed that no worship should be performed, no oblation offered, no gifts bestowed upon the Brahmins. "I, the king," he said, "am the lord of sacrifice. Who but I am entitled to the oblations?" In vain the Rishis remonstrated. The godless Vena would have none of it, and the pious Munis decided that they must kill him, as he was not fit to reign over the earth. "So they fell upon the king and beat him with blades of holy grass, consecrated by prayer, and slew him who had first been destroyed by his impiety towards God." Vena being dead without offspring, the difficulty arose that there was no one to rule and maintain order in the land, and the Puran goes on to detail how the sages consulted together and rubbed the thigh of the dead king to produce a son. "From the thigh thus rubbed came forth a being of the complexion of a charred stake, with flattened features, and of dwarfish stature." "What am I to do?" cried he eagerly to the Munis. "Sit down" (*nishida*) said they, and thence his name *Nishada*. His descendants, the inhabitants of the Vindhya mountains, Great Muni, are still called Nishadas, and are characterised by the external tokens of depravity.

This tradition is also repeated in the Bhagavata-Purana (see Burnouf's translation IV. 14,43, 46), while the Padma Purana (Bhumi Khanda) has a similar description, adding to the dwarfish stature and black complexion, a wide mouth, large ears, and a protuberant belly. It also particularises the posterity as Nishadas, Kiratas, Bhillas, and other barbarians living in woods and on mountains.

Past and Present.

So much for unalloyed tradition. Tod remarks that we can trace the Bhils as powerful communities as far back as the "Mahabharata," when they were lords of all the countries through which they are now sparsely scattered and much else besides, and extended northwards to the sandy plains of Jodhpur. The name Bhil is immortalised in the "Mahabharata," where it is stated that a follower of the Bhil chief of Maheshwara on the Narbada (the modern Mahesar) slew with an arrow the demigod Krishna on his retreat towards Gujerat after the celebrated battle of the Kurus and the Pandus.* Dunji, who ruled in Malwa in ancient times, is deemed by most accounts to have been a Bhil, and his descendants maintained the dynasty for nearly 400 years until ousted and conquered by the great Rajput tribe of Puar.

* *Cf.* Census of India, 1901, vol. i A., p. 318, Table XIII.

† *Cf.* Vishnu-Purana, Wilson's Book I, chap. 13, Translation, Vol. I., pp. 179 *et seq.*

* Malcolm's "History of Central India."

Authentic records of the Udaipur and Jodhpur families show that large tracts of these States were conquered from the Bhils, and the same is the case with the Jhabua State in Central India, which as late as A.D. 1550 was a small Bhil kingdom, and then passed to the ancestors of the present Rajput chief under a grant from Akbar, on the conquest of the Bhil ruler by the Rajput leader.

From the above it seems evident that in remote times, prior to the establishment of the great Rajput kingdoms of Western India, the Bhils were the ruling race; that with the advance of Aryan civilisation they were gradually driven more and more into the hilly forest tracts; and that this process of expulsion, absorption and subjugation continued with more or less vigour until the establishment of British supremacy in the early years of the nineteenth century, when, so to speak, the fluidity of rights and tenures on the Indian Continent was arrested, and each one was confirmed in what he had. By that time, however, the Bhils had long lost all independent power. They were to be found only in the wild districts above enumerated, nominally subordinate to the native chiefs. Agriculture was practically unknown among them, and they lived almost entirely on the products of the chase and of the jungle, supplemented by the profits of loot and blackmail, which they levied whenever possible on all who came within their reach. Whatever their true ethnological origin may be, and on this point there seems little doubt that the basis of their race is non-Aryan, they have largely lost the physical characteristics so minutely described in the Vedas. True it is that in the more distant districts, individuals and even whole families of this unattractive type may still be found, but the mass of the race are far from unattractive. They are small but well proportioned, both men and women —lithe and active, and their features not irregular. The various types which are met with undoubtedly prove a large admixture of Aryan (principally Rajput) blood, but to whatever degree the physical type may have altered, their mental outlook is but little changed, and to this day the Bhils have remained a class apart—despised, though at the same time feared, by the Hindu population, and themselves intensely suspicious of civilisation in any form, or of any system or administration which might tend to restrict their absolute freedom of movement.

In the wilder tracts, where the native administration has changed but little with the course of centuries, their country is only on rare occasions visited by the native officials, and in some places the only meetings that take place between the authorities and the subjects require special protection in the form of an oath (*bachan*) for the safe conduct of the parties.

In parts where, for various reasons, the administration has been stronger during the last forty years, the Bhils are losing some of their independence of nature, and gradually becoming more amenable and more useful members of society—more peaceful and settled in their relations with the authorities. Even in these parts, however, they need very careful handling. They still have that primal characteristic of an uncivilised race—an extraordinary suspicion of anything which tends to change their traditional form of life. An ill-considered or premature reform; a greater strictness or even a change in the system of revenue collection; an epidemic or any misfortune in their house or village which appears as a visitation of the evil spirits—any of these things is sufficient to cause wholesale emigration, either to the jungles, when robbery and murder will immediately increase, or to some other jurisdiction where they may hope to find more congenial or auspicious surroundings.

Their villages are typical of themselves. Instead of the agglomeration of mud huts, each adjoining the other and crowded as closely as possible into a given space, which may be taken as a type of an ordinary Indian village, the Bhil's hut stands alone, completely enclosed with a high-thorn fence. For choice it is perched on a hillock, and is surrounded by the fields which the owner cultivates. The nearest neighbour is probably 200 or 300 yards away, similarly detached and isolated, with bits of jungle intervening.

Bearing on this point and on the great desire of the Bhils to be left alone, I remember on one occasion in a very wild part of the country coming across a carefully-prepared threshing floor in the middle of the forest. It was in December, and a Bhil with his family was busy threshing the autumn crop. There was no hut or dwelling-place of any kind in sight, so I asked the man where he lived and why he did his threshing in the jungle. "Oh!" he said, "my home is over there," pointing through the forest, "and we make the threshing floor here because here we are not troubled." I subsequently found the house in a clearing about three-quarters of a mile

away. There is undoubtedly a method in their madness, and they have taken the measure of the average native subordinate, who, coming to a hut of that kind on State business and finding it apparently deserted, will probably be content to report that the owner has emigrated.

Headmen.

But though the control exercised over individuals by the various durbars is often very slight, the Bhils have a strict sense of obedience to their own headmen (tarvis, patels, or zamindars as they are variously called) and it is in consultation with these, and through these, that the orders of the durbar are framed and carried out. In the best administered tracts these headmen are persons of much importance and prior to the recent famines of considerable wealth. In return for free grants of land and cash payments which they enjoy, they assist materially in collecting the yearly revenue, which is calculated on the number of ploughs (*i.e.*, pairs of bullocks) that a man possesses; they advise as to whether and if so to what extent any remissions of revenue should be granted; it is their duty to report crime and to track and arrest the criminal, and when necessary individuals or whole villages are called in through their agency to meet the officials. They also in many cases form courts of arbitration (*panchayats*) for the settlement of disputes arising among their clansmen, the verdict of such tribunals being accepted im-implicitly by the parties.

An influential headman can easily collect in two hours an armed following of 200 to 300 men. It will, therefore, be readily understood that, in the Native States, where the central authority is usually but weakly felt, these people exercise much weight. They are indeed the intermediaries between the subject and the ruler, and the fact that their rights are hereditary naturally tends to increase their dignity and influence.

Moral Qualities.

As to the moral qualities of the race, great simplicity and a certain natural fearlessness of consequences are qualities which immediately induce sympathy in a European mind, but which, at the same time, cause them much trouble in their dealings with their more astute fellow Indians. Again, up to a certain point, and especially in the wilder tracts, where they have not been contaminated by what we may call the "criminal classes," they are extraordinarily truthful. On many occasions it has been my duty to try Bhils for offences of every degree of seriousness, from murder or *dakaiti*, through all the gamut of the Penal Code, down to ordinary assaults or thefts. In the great majority of cases arrest was followed by confession, not of a half-hearted kind, but accompanied by a full *exposé* of reasons for the crime. So much is one impressed by this extraordinary simplicity that, except in cases where habitual criminals are concerned, the denial of a charge by a Bhil would form the strongest evidence he could produce in proof of his innocence.

The family ties in ordinary times are strong, and though chastity in an unmarried girl is not, perhaps, so common as it should be, adultery on the part of a married woman is a serious offence which, under the best of circumstances, entails a heavy fine on the co-respondent, and if aggravated, as sometimes happens, by insults offered to the aggrieved husband, will almost invariably entail the death of the erring wife or the co-respondent, or both, at the husband's hands.

Cruelty or premeditation is not, as a rule, common, except in cases of this kind or where superstition has been at work. A typical case of the effect of the latter may perhaps be of interest. A man had lost his wife and two or three children through disease of some kind—probably from some form of vegetable poison in the wild roots which, especially during hard times, constitute a large portion of the Bhil's diet. In the neighbouring village, there lived an old aunt, who, for no reason, apparently, except that she was old and, therefore, perhaps, very ugly, became a subject of suspicion to the bereaved parent. Possibly an absence of active sympathy, not uncommon in old people, may have enhanced the suspicion, but in any case the man was satisfied that his aged relative had the evil eye and had thereby caused his misfortune. Taking two companions with him to guard the exits from the hut, he proceeded there in the dead of night and found the old lady asleep. Without further ado, and in perfectly cold blood, he battered her to death as she lay on her bed, while her husband was knocked down and met a similar fate at the hands of the men outside. Having taken what he regarded as his just revenge, he returned to his own village and gave himself up to the headman, stating in full detail all that had occurred.

Other Characteristics.

The Bhils are naturally of a gay disposition. They have a keen sense of humour, and can laugh better than most Indians. On all possible occasions they are ready to dance and sing, and indeed nothing is more characteristic of the country than to see a crowd of 200 or 300 Bhil men and women enjoying themselves in this way. Broken up into groups, they perform with great correctness and often with much grace various forms of dance to the accompaniment of primitive instruments of the drum and cymbal type, singing the while either traditional songs of famous Bhils or others of a more or less religious kind suitable to the occasion. At first the men and women will dance separately, but as the evening wears on, and the wine, which is an invariable accessory, begins to take effect, the men and women dance together until the excitement reaches a somewhat dangerous point, when the women withdraw from the circle and use their influence to calm their more excited male relatives.

Among the Bhils the women are generally more intelligent, and have a far greater fund of common sense, than the men. They exercise in many cases a predominating influence in their homes, and have practically the entire management of the house. It is they who urge moderation on their lords and who intervene, often successfully. in quarrels arising under the influence of liquor. Though drinking is the great curse of their country, and a drunken Bhil on market days is the commonest sight, the women are sober and very seldom indulge to excess.

To all manual labour the Bhils have an inherited dislike, and their agriculture is consequently of the most primitive kind. In former times the system known as *walri* was very largely practised. In its essential features this consists of burning a patch of forest, and sowing the crop with little or no tillage in the ashes. Sometimes such a clearing would be used for three years in succession, but often the clan moves every year to a fresh field. The wanton destruction thus wrought is, of course, enormous, as, in addition to the timber trees deliberately burnt to clear the soil, the fire not infrequently runs wild through scores of square miles of forest. In the wilder tracts this system is still to be seen in practice, but, with the spread of a knowledge of forestry, the Durbars are endeavouring to stop it completely, and to induce the Bhil to settle as permanently as may be on the lands he cultivates. Even when this stage has been reached, however, his cultivation is generally limited to a single ploughing of the field after the rains have fallen in June, sowing the seed, one weeding, and the reaping and harvesting in October and November. With the produce so obtained the State demand is paid, new clothes are bought, and the remainder is stored for the food supply of the year.

The costume of the men is of the most scanty kind, and is generally limited to a small piece of cotton cloth passing between the fork and covering the loins and fastened round the waist to a thick thread; another small piece of the same material is bound round the head, forming a scanty turban, but leaving the crown quite bare. In addition a light cotton sheet is thrown over the shoulders, and this is used as a covering at night. One must not, however, forget the bow and arrow, which to this day the Bhil invariably takes with him in the forest or when moving from place to place. They are ordinarily barefooted, but sometimes wear sandals consisting of a leather sole fastened to the foot with string or bark. In spite of their scanty attire, they are vain of their personal appearance, and on festivals and such occasions bestow much care on the oiling and dressing of the hair, which is worn long and carefully combed; the wooden native comb and a small mirror being stuck jauntily on the side of the head between the folds of the *pagri* and the hair.

The women are usually well dressed, the whole body from the knees upwards being covered with the usual body cloth and head covering, and a short coatee over the breasts. Both the sexes are fond of jewellery and when times are good heavy silver ornaments are often to be seen. In certain parts of the country the women also wear heavy brass anklets about 1½ to 2 inches broad, one above the other, so as to completely cover the leg from the ankle to the knee. When dancing both sexes wear anklets with bells to mark the rhythm of the step.

Aversion to Manual Labour.

But to revert to their objection to manual labour. Rather than work as labourers or coolies they will go without food or live on the coarsest substances such as roots, leaves and other wild produce of the forests, and when not otherwise engaged they will roam over the forests in search of edible or other economic products for home consumption or for barter or sale. For instance, the Mohwa tree (*Bassia*

latifolia), which is fortunately so common throughout large areas of the Bhil country, is a perfect mine of wealth. Its flowers and seed are both most valuable. The flowers (*corollas*) provide a very large proportion of the Bhil's food supply. They are eaten fresh, dried, and also cooked with parched grain. In the spring when the buds appear whole families temporarily migrate to the jungles for the "Mohwa harvest." The ground round the tree is carefully cleared, and as the flowers fall they are collected and stored. When dried they are sold in the bazaar for the liquor trade, and it is from these that practically the whole of the native liquor consumed in Central and Western India is distilled. In times of scarcity the monetary value of the mohwa flower rises with the intensity of the distress, and it often becomes of vital importance. In former years there was a large export of the flowers to France, where they were utilised for the manufacture of brandy, but the importation has, I believe, now been prohibited.

The mohwa seed contains a valuable oil, which is used locally for cooking, for burning, and medicinally for application in cases of skin disease. A large quantity is exported annually to France, and doubtless contributes considerably to the world's supply of olive oil; it is ostensibly intended for the manufacture of soap. Further, a white milky juice is obtained from cracks in the bark, and the bark itself is often utilised for dyeing purposes, while the flowers, in the form of a decoction, provide a medicine largely used and much appreciated as a stimulant, an astringent, and even as a cough mixture!

With all these many properties it cannot be a matter for surprise that the mohwa tree is regarded as sacred by the Bhils, and that it is almost the only tree of the forest that they will not either cut or destroy. It is jealously guarded as the personal property of the holder of the land in its neighbourhood, and it is only in the depths of the forests that the first comer has the right to sit down under the tree and collect the crop.

Second to the mohwa, comes the mango (*Mangifera indica*), which is also a common forest tree in these parts. Then the chironji (*Buchanania latifolia*), the nuts of which are much prized, and which are the common substitute for almonds in native confectionery; this crop is carefully collected by the Bhils and used as food, but, as in the case of the mango crop, it is more generally sold in the markets. The temru (*Diospyros Melanoxylon*) with its fruit about the size of a plum, and the tinis (*Ougenia dalbergioides*), the leaves of which are in very large demand in the Bombay Presidency as a covering for native cigars and cigarettes, are specimens of the many trees which add to a Bhil's income and afford him congenial occupation throughout the spring and summer months.

The rooted objection of the Bhil to manual labour was markedly and disastrously shown in the great famine of 1899-1900. For the first time within living memory these wild areas felt the full force of an almost complete failure of the south-west monsoon, with the result that not only were the cereal crops entirely destroyed, but, owing to the lack of moisture, the wild roots and bulbs and even the grass failed to germinate. In spite of this, it was a matter of the greatest difficulty to induce the Bhils to take advantage of relief works opened for them. They preferred to sell all their ornaments and jewellery, so that the country bazaars were rapidly flooded with articles of this kind, and silver ornaments became a drug in the market. The household utensils then suffered the same fate, and when everything was exhausted, the Bhil either took to the war path and looted far and near wherever opportunity offered, or, if wanting in energy, wandered off into the forests, probably to die.

When one thinks that the price of the staple food—grain—in their country varies in normal seasons from 60 to 80 lbs. to the rupee, and that during the recent famine years the price averaged between 16 to 25 lbs., or, in other words, that a penny loaf cost 4d., or for some months 5d., there is little cause for wonder that the inherited marauding instinct of the race should make itself felt, and that peace and security of property or person should disappear until a return of normal seasons removes the necessity for crime.

These conditions, as I have observed, were specially marked in 1899-1900. In the following years, when distress continued in certain parts, and when relief operations were again necessary, it was found that there had been a great change. Many had learnt their lesson, and in 1902 in one State where in 1899 the people had especially suffered, there were thousands of adult Bhils, men and women, working well, and regularly on relief works on a minimum wage of 20 to 24 ozs. of grain a day.

But the place where the Bhil is at home,

and where the characteristics of his race may be seen to the best advantage, is in the forests. It may be said that his primary instinct is to hunt. Invariably carrying his bow and arrows, he will cover great distances, walking or running, and nothing in the form of the game is too lowly for him. An unannounced visit in the neighbourhood of a village will often reveal the men and boys hunting hare, pigs, foxes and even cats, and they have been known to run down sambhur, blue-bull (*nilghai*) and bear. Their senses of sight and hearing are highly developed, and they are splendid trackers, either of man or beast. While in the forests they fear nothing; in towns and outside their own country they become timid and uncertain of themselves, and will allow themselves to be bullied by the smallest urchin of the place.

Tribal Divisions.

The race is divided into a number of tribes, each tribe being again divided into an almost endless number of exogamous septs or clans. In all, I believe, there are 114 different divisions of this kind. The principal tribes in Central India and Rajputana are Rathia, Pouria, Patlia, Tarvi, Naik, Damar, Nanama, Daima, Akaria, Khararia, &c. The Rathia tribe is divided into ten exogamous clans—Bondar, Solia, Sastia, Jamra, Khaitia, Awaya, Bamnia, Nargaon, Chouhania, Kiraria, and Chougria. The Rathias are supposed to have been the original inhabitants of the Rath country, which now forms the greater part of the Ali Rajpur State in Central India and includes Jobat and part of Chota Udaipur State in the Panch Mahal district and the thakurates of Kathiwara and Ratanmall.

The Naik tribe has eight exogamous divisions — Mowla (lion), Solia (bird), Pawar (pigeon), Chohan, Beria, Nikam, Bagul, and Nairia. They claim descent from Khande Rao, one of the many avatars of the god Vishnu, and are generally supposed to have had their original abode in Khandesh. They are, perhaps, the most warlike and most formidable of all the Bhil tribes, and on the least provocation are ready to return to their old habits of plunder. They are to be found principally in the Western Satpuras and on the banks of the Narbada, in the wild country where that river divides the Satpuras and the Vindhyas, and in these parts they still receive payments from the States in consideration of good behaviour and for keeping the passes and fords open. In addition, in many places they receive a toll of 1—2 annas from travellers passing through their settlements. Several of the Naik clans are totemistic and highly reverence the totem from which they are descended. This also applies to other clans. Thus they will not kill, eat, or cut the bird or animal to which they belong. They swear by it and are usually tattooed with it on the chest and arms. The usual fine for a man who insults his totem is Rs. 5.

The Tarvi tribe is sub-divided into 17 clans as follows:—Mohinia, Daitya, Dwarkia, Bhamnia, Daoria, Varkla, Maoria, Mari, Bondria, Massania, Vasbia, Ajnaria, Vasnia, Berja, Singaria, Pachao, and Kikria.

The monkey is to them very sacred and is regarded by many as their ancestor. They consider themselves as aboriginal to the forests of the Satpura, Vindhya, and Aravali mountains. Their principal deity is the snake god (*Bhilat deo*). The tribe is very numerous and indeed, as will have been observed above, their name has, in many parts of the country, become synonymous with that of headman: in other parts the tarvi of the village is more the village watchman, whose special duty it is to act as guide to travellers or to carry on the tracking of criminals or stolen cattle which may be traced up to the limits of the village. A large and important section of the community are the Bhilalas. These, as their name implies, are half-bred Bhils, and are the descendants of Rajput men and Bhil women. They consider themselves as superior to the Bhils to the extent that they will not eat with them, and, indeed, are generally better favoured by nature, both physically and mentally. The Bhil, however, does not regard them with any special respect, and if he thinks of the matter at all, the tendency is to despise them slightly as half-castes.

Religion.

The religion of the Bhil is, as I have said, animistic, that is, "he has a tendency to worship with a view to propitiate anything he does not understand, such as the manifestation of great power or an object of unusual shape or form."* This definition, however, hardly covers all the objects of his veneration. The respect and reverence which Bhils pay to valuable forest trees such as the mohwa, the teak (*Tectona grandis*), the pipal (*Ficus religiosa*), the banyan (*Ficus bengalensis*), the sal (*Shorea robusta*), and the anjan

* *Cf.* Bombay Census Report, 1901.

(*Hardwickia binata*), all of which largely assist them in their struggle for existence, show that ideas of utility count for much in the matter. Purely animistic worship, however, such as that devoted to the earth, the sun, the great rivers, some special mountain peaks, a rock or stone of curious shape. or even a solitary mound rising from the plain is general; also the worship of animals, but in this case the animal venerated varies, as already remarked, with the totem of the tribe. Then, too, although a Brahmin is nothing to a Bhil, the Hindu pantheon is not altogether neglected, and the terrible Kali, Ganesh the elephant, and Hanuman, the monkey god, are common objects of reverence.

The following are the names of some of the principal gods and goddesses worshipped by the Bhils in the Jhabua State in Central India :—1. Hatipowa,—as the guardian of village cul-cultivation at the Hindu festivals, Diwali and Dassera in the autumn. 2. Waghacha Kumvar, against ravages of wild beasts. 3. Khorial Mata, for protection of cattle. 4. Halk Mata, for success in plundering expeditions (with the spread of the *Pax Britannica*, this worship must necessarily have diminished, though she must have had many devotees during the recent famine). 5. Devi Kanail, for good harvest. 6. Behia Baji, for rain. 7. Ghora Raja, against attacks and plunderers. 8. Chamunda Mata, goddess of harvest; first fruits are offered to her. 9. Bhubhai Mata, in times of epidemic disease. 10. Sitla or Sita Mata, goddess of small-pox.

The names of most of these probably vary in different parts of the country, as in each tribe the origin of the deities varies; but Hatipowa, the guardian of cultivation, Khoria Mata, the protectress of cattle, and Chamunda Mata, the goddess of harvest, are commonly found, while Sita Mata is probably the recipient of more veneration than any other object in the Bhil country. Outside of almost every village, if possible near the boundary, under the shade of a banyan tree, against which leans some queer-shaped stone smeared with vermilion or black lead, will be found a heap of broken pottery, consisting of earthen water vessels, animals in the shape of a horse, or little human figures, hollowed out to hold the offerings of grain. Such is the shrine of the dreaded Sita Mata.

Temples in our acceptation of the word do not exist. The images or idols, if they exist at all, are usually pieces of shapeless stone, smeared with an oily mixture of vermilion or black colour, placed in a grove of trees; or even some great tree will suffice to represent the deity, and the only outward sign of sanctity may be strips of cotton cloth tied to its branches. The worship itself usually consists of a feast at which fowls or he-goats are sacrificed, to the accompaniment of songs and music performed by rawals or dholis, the bards of the race. The idol receives a fresh smearing of oily colour and a small portion of the sacrificial meat with a little grain is burnt before it. The remainder of the flesh is then divided and the feast continues with the consumption of much liquor, the bards receiving their share. On greater occasions, as for instance at the worship of Hatipowa at Dassera, a bullock is sacrificed, doubtless in imitation of the Hindu custom. Again, the first ceremony of a marriage, when the negotiations are proceeding between the two families is a libation offered to the great goddess Earth, to ensure her blessing on the marriage that it may be fruitful and fortunate. In this case one rupee is placed on the ground by the bridegroom's representative between the contracting parties, and on the rupee a little wine is poured. When the negotiations are concluded the tarvi of the village has the right to this rupee.

The most auspicious days for worship are, it appears, Sunday and Tuesday, while Tuesday and Thursday are auspicious for the commencement of agricultural operations after the rain has fallen.

Finally, the Bhils believe that for at least three days after death the spirits of the departed are free to wander on the earth, and that, unless appeased with suitable worship, they may seriously affect for evil their relations or acquaintances. During this period they are supposed to dwell in trees, especially in those of the valuable species above-mentioned, and thus also we find another cause for the veneration with which these products of nature are regarded.

SOCIAL CUSTOMS.

Throughout the race marriage is deferred until an adult age, usually 18 for boys, and 15 or 16 for girls. Unchastity in a girl is generally tolerated on the understanding that if she becomes *enceinte* it is condoned by marriage. Polygamy is permitted, but as the wife brings no dowry, it is largely a question of means. The re-marriage of widows is also allowed in most tribes, and she may and does often marry her deceased husband's brother.

Adultery in a married woman entails divorce, if nothing worse, and the divorced woman may marry again under a special form known as *natra*, for the consummation of which no special ceremonies are needed and the woman does not enjoy the full status of a lawful wife. The laws of marriage are endogamous within the tribe, but strictly exogamous as regards the septs or clans. Thus a Naik must marry a Naik woman, but he must not marry into the sept to which either his father or his mother belonged, nor anyone within two degrees of relationship on either side. In some cases, amongst the Tarvi tribe, for instance, marriage is determined by a regular courtship, and in others, where the bridegroom is very poor, he follows the example of the patriarch Jacob and goes and works in the bride's house for seven years. The couple, however, live together as man and wife from the commencement; no money is paid on either side, and the son-in-law is accepted more or less literally as a son in his new home. The general rule, however, is that the marriage is arranged by the parents of the young couple, after confidential inquiries have been made on both sides. Money is paid by the bridegroom's family for the bride. The ordinary amount in former times in the Jhabua State, for instance, was Rs. 90 of the Salim Shahi coinage, in lieu of which British Rs. 45 are now accepted. Out of this money, clothes and jewellery for the bride are bought to the extent of about half the sum, and the remainder is divided amongst the bride's family. It will be observed that this system is directly opposed to all Hindu law and custom, under which, according to the Shastras, all expenditure should, if possible, be on the side of the bride's family, and a dowry should be given, and where the principle that a girl can (so to speak) be bought by the bridegroom's family is regarded as highly improper. There would seem to be little doubt that it is a relic of pre-Aryan civilisation. In his "History of European Morals," Lecky deals fully with this subject. I need only remark here that the immediate practical result is that amongst the Bhils the birth of a girl is in no way deplored, and indeed is a matter for congratulation; the exact converse of Hindu society, where the birth of a girl is regarded as a nuisance, if not as a calamity, and in former times was not uncommonly the cause of much infanticide.

The ceremonies now to be detailed are those in force amongst the Bhils of Jhabua, a State situated practically in the centre of the Bhil country. As with their worship, their customs also probably vary in detail in different tribes, but the general system may, I think, be accepted as common to the race.

If the confidential enquiries made by the bridegroom's family are satisfactory, a formal "embassy" is sent to the bride's family to settle the betrothal or *sagai*. This embassy consists of three or four men, who come fully armed with their bows and arrows, &c., and sit down outside the bride's house. Before proceeding to business, the libation to the earth, which I have mentioned above, is made. Each party has previously brought with it its own wine, and when the libation has been performed the tarvi of the village gives permission for the wine to be mixed and appoints two men, one to mix it and the other to distribute it; the former receives eight annas, and the latter four annas from the bridegroom's party.

When the details of the betrothal, *i.e.*, the sum to be paid by the bridegroom (known as *dehaj*) have been settled, the father presents the bride with some jewellery usually a nose-ring and a necklet, and the marriage is regarded as fixed when the *dehaj* has been paid. The actual days for the performance of the ceremony are decided on after consulting the old men of the clan. The stars are specially considered, but there is no need whatever for astrologers or Brahmins, the latter being never employed by the Bhils.

Before the bridegroom's procession starts from his house or village, a certain period, from three to nine days, according to the wealth of the family, is passed in feasting and singing, &c. The period so fixed is always an uneven number of days on which only the ceremonies are performed. No work is done, and as many days as are spent in this way, for each day a piece of haldi (*Curcuma longa*) root (turmeric) is tied by a tri-coloured thread to an arrow shaft and sent to the bride's house, where similar ceremonies for a similar number of days must be performed. During this period the special ceremony of *notra* is performed at the bridegroom's house. Invitations to attend it are issued to relatives and clansmen by messengers, usually *dholis*, who leave a handful of rice on the threshold of the door of each invited guest's house. The bridegroom receives his guests seated in a pavilion (*mandwa*) with a plate in front of him, in which his relatives place their presents (*notra*) varying from one to five rupees, while his clansmen give

similar presents of from two annas to one rupee.

All preliminaries being duly performed the procession starts for the bride's village, and on reaching the boundary word is sent to the bride's father that he should come out with his relatives to take the usual *laq*, *i.e.*, certain payments over and above the *dehaj* or betrothal money, which now fall due. These payments, which are as follows, are then made in the presence of the village tarvi :—

Due to the Durbar	R. 1·4·0	
The tarvi of bride's village ..	R. 12	Salim Shahi
Bride's mother	R. 12	,,
,, maternal uncle	R. 12	,,
,, paternal uncle	R. 12	,,
,, brothers	R. 12	,,
,, sister	R. 2	,,
,, paternal aunt	R. 2	,,
,, village dholis	R. 12	,,
The tarvis of neighbouring hamlets	R.	1 worth of wine
Eunuchs*		8 annas
State Purohit (priest)		8 ,,

It will be readily surmised that in regard to all these payments cash is not often available, so the matter has to be settled by the barter of buffaloes, bullocks, goats, &c., or even mango or mohwa trees may change hands in this way. After the payment of the *laq*, a feast is given by the bride's father. The bridegroom then goes to the bride's house, and touches the *toran*, or garland, which decorates the entrance, with his sword, paying a fee of 4 annas to the village *kotwal*, or policeman. He then advances towards the pavilion (*mandwa*) of the bride, but is stopped by the bride's brother, who places his foot on the bridegroom's foot; on payment of 8 annas he is allowed to proceed. He next seats himself in the pavilion and the bride is brought out of the house. She is clothed in white, the border of the garment being stained yellow with *haldi*. She wears a crown of tinsel (*mor*) on her head and her hair is allowed to hang down her back. The bridegroom is also simply dressed in white. The *sari* (head-covering) of the bride is now tied to the bridegroom's pagri, and the two sit down facing the East, the bride on the left. A small bundle, consisting of a little rice dyed with *haldi*, one pice (¼ anna), and a betel nut, the whole wrapped in a mango leaf, is then given to the bride by her sister-in-law or aunt, and she is told to hold it tightly. A cloth is placed over both their heads and the groom is told to take the mango leaf out of the bride's hands, using one hand only. This is duly done. The *phira-phirni* ceremony is then performed, which consists in the couple, tied together as they are, circling round a peg (*choura*) driven into the ground. They complete the circle seven times from right to left, the bridegroom leading four times and the bride three times. This is really the essential part of the marriage ceremony, and they are regarded as married when this has been performed. But much else remains to be done. Still tied together, the couple are then taken to the village refuse heap (*ukeri*), in which previously one of the family has hidden a small basket (*potli*), two to three inches square, containing one pice, a betel nut, and a little rice. The bride and bridegroom are now required to search for this basket. If the bride finds it first the women of her family praise her, and suitably abuse the female relatives of the bridegroom. If fortune is with the bridegroom the women of his family pay the same compliments. The tarvi of the bride's village then proclaims as follows to the bridegroom's party :—"This girl has now been given to you. If her character is bad you must inform me. If any of you kill her by sword, or arrow, or stick, her family will take the revenge of blood. If she die a natural death, there will be no claim against you." The tarvis of the bride's and bridegroom's villages then drink together. The groom's party retires to wait on the outskirts of the village, and the bride is taken back to her home, where her hair is tied up and arranged by her mother. This is the last thing to be done, and she is then taken by her brother to join the groom's party. Accompanied by her brother, she returns with the bridegroom to his village, where the *ukeri* ceremony, or searching of the refuse-hill, is again performed. After this the friends and relatives separate to their homes and the couple are left in peace. It is considered proper that after three or four days the bride should return to visit her own family. For this purpose her relatives come to fetch her, and a feast is given by the bridegroom. She stays at her own home for about five days, and then finally quits it for that of her husband.

Each stage of the marriage ceremony is marked by special songs, sung by the women of the family, with the assistance of the minstrels (*dholis*) specially engaged. A collection

* A few eunuchs still exist in the Bhil country, and, indeed, throughout Native States. They are degraded Mohammedans, never Bhils.

I have made shows that they are usually vulgar, if not obscene, the main point being the abuse of the female relatives of the bride or bridegroom, as the case may be.

Those who are acquainted with Hindu, especially Rajput, marriage ceremonies, will probably find several points of resemblance to the Bhil ceremonial. The *mandwa* or pavilion, the touching of the *toran* or garland by the bridegroom with his sword, and the ceremony of circling the *choura* are essentially Hindu in their origin, and have doubtless been assimilated by the Bhils in the course of centuries of contact with the neighbouring Rajput races. Indeed it would seem probable that the patriarchal system under which a man worked for his bride in her father's house was originally more general, and that only with the increase of wealth and under unavoidable pressure of neighbouring Hindu influence, the complicated and somewhat expensive ceremonies I have described have been evolved.

I turn now to the funeral ceremonies. Infants are buried. In the case of adults also if the death is due to cholera, small pox, or leprosy, the body is buried—otherwise it is burnt. In writing of the Bhils, in 1820, Sir John Malcolm notes that they bury their dead, but except to the extent above mentioned, all my information goes to show that cremation is the ordinary system in force. The following is a description of the ceremony as now practised in the Jhabua State. The death is announced to the village by the firing of guns and beating of drums. The hair of the corpse is dressed as in life, and the body washed with water, brought in a new earthen vessel (*gharrah*) and clothed with new garments. A little dough is then mixed with the left hand and cooked on one side only. This is placed in a cloth at the side of the corpse. The spot in the hut where the man died is freshly plastered over with mud (*liped*) and a small lamp made of dough is set burning there under cover of a basket. A bier is prepared of bamboo poles, at the head of which cocoa-nuts are put, and the corpse is carried to the burning place, which if possible is near some running water. One pice ($\frac{1}{4}$ anna) is also tied in the clothing of the corpse to pay the rent of the land on which the body is burnt. This is not necessary when the body is that of a headman or a headman's wife. On the way to the burning-ground a piece of burning fuel is carried by a close relative, and if the deceased was an important person, guns are fired and drums are sounded. When the village banyan tree or other prominent tree in the neighbourhood is reached, the procession halts and rests. Each person in the procession picks a leaf of the tree, and these are all collected in a heap. The relatives also tear off small strips of the deceased's clothing and tie them on the branches of the tree. The new water vessel used for the washing of the corpse is carried to this spot and thrown on to the heap of leaves. If a widow is left she is brought here by the women of the family and her silver ornaments are removed. The lac ornaments are broken.

On arrival at the burning-ground the corpse is placed near water and all employ themselves in piling up the funeral pyre. The body, after being again sprinkled with water, is then placed thereon, its head to the north and feet to the south. The face is uncovered, and in the mouth is placed one rupee, a piece of the half cooked bread, a blade of grass and a little water. Minute pieces of sandal wood, or if that is not available, wood of the pipal tree, are then placed by everyone on the chest of the corpse, and the pyre is lighted by two near relatives, who while doing this turn their faces away. The corpse's ornaments, except those of gold, as also his bow and arrow, are burnt with him. Once the pyre is lighted the party retires to a distance and waits for some hours until the burning is finished, when all wash themselves and their clothing. They then return to the house, where a little bread and wine is taken, the latter by the men only. An agreement is then come to with the rest of the village as to the extent to which the death shall be celebrated by feasts, but with the family the period of mourning may be said to last for fifteen days. For the first three days the mourning extends to the village also, and no wedding can take place, nor will the actual participants in funeral ceremonies do any other worship to the gods. On the other hand, they will mix freely with the rest of the village, and there is no idea of that defilement which, in the view of the Hindus, follows from contact with those who are engaged in these ceremonies. For the first three days worship is done at the banyan tree, food being left there for the dead. On the first and second days also, the lamp under the basket is carefully kept burning. On the third day, the pyre is extinguished and the ashes scattered and thrown into water; the ground is also cleaned and plastered. Any bones that may have remained unburnt are washed and put into an earthen vessel and buried near the house. These,

however, are exhumed on the twelfth day and are then taken and thrown into the Narbada or any other of the larger rivers which flow through the Bhil country. On the third day also, the lamp is removed and carefully examined to find any marks there may be underneath it, as these marks are supposed to show the form of life into which the dead man has now returned. For instance, if in any way the shape of a man's foot can be detected, he has been reborn as a human being; if there is the resemblance of a goat's foot or a scorpion's tail, &c., then as a goat or scorpion. After this examination the lamp is thrown away and the whole house is freshly plastered inside with mud. Nothing is done from the fourth to the eleventh day, but on the latter a miniature pavilion or swing, or both, is erected by the heir near the house, and on this a ball of cooked rice is put. On the eleventh, twelfth and thirteenth days the heir is required to eat his food without salt. On the fourteenth day the rawals (minstrels) are called in to sing. On the fifteenth day there is a general feast, and on the sixteenth day all the relatives return to their homes. The rewards bestowed on the minstrels are on the following scale:—One hookah, one charpoy or string bed, nine cubits of cotton cloth, one pair of shoes, a calf, or five rupees. For every cocoa-nut broken, two annas; for every betel nut, one anna. If the family is rich, a mango or mohwa tree is in some cases also presented. A *pagri* is given to relatives.

A few words may be added in regard to the swing or pavilion which the heir is required to erect on the eleventh day. The intention is obvious, being for the repose of the soul of the deceased. Sometimes one finds on the side of a forest path a swing in miniature beautifully made of split bamboos, with a few grains of rice and pieces of cocoa-nut underneath, or a piece of thread stretched from the top of two bamboo sticks to represent the ridge pole of a hut. In other cases these erections are of natural size and of quite a permanent character. One I remember well. In this case the full-sized swing was suspended with iron rods, there was a long, stout bench for the body to rest on, and over this, supported by strong wooden uprights about the height of an ordinary hut, ran a strong piece of wire representing the ridge pole of the habitation where the spirit might rest protected from the elements.

In the case of a well-known and influential headman a permanent memorial is sometimes erected. These may take the form either of wooden posts driven into the ground, the tops of which are roughly decorated, or else what is known as a Ghatta or Tarvi stone, which is so frequently to be seen near villages in the Bhil country. The Tarvi stone is a flat slab of stone standing about 2½ to 3 feet out of the ground and bearing on one side a roughly carved representation of a Bhil riding on a horse. Though the Bhil in his natural state never rides, there is a widespread reverence for the horse both on account of legends which exist in regard to it, and also probably by reason of its rarity and value throughout the country, and hence presumably the great departed are exalted in this way. In one instance I heard of a stone representing the dead hero riding on an elephant, but this I believe is a unique specimen.

MINSTRELSY.

I have referred more than once to the rawals and dholis, the minstrels of the Bhils. These two classes are the repositaries of the Bhil traditions. They take the place of priests and are in request on all ceremonial occasions when they chant religious or heroic songs. The rawals are especially employed in times of mourning; the dholis at marriages or births, &c. The two classes are generally considered as having sprung from the Bhils, but as they have forsaken the normal independent Bhil life and taken to minstrelsy and begging, they are, though indispensable, now regarded as of a lower order. A Bhil will not marry with either of them, nor will he eat food cooked by them, though ordinarily they have no scruples on either of these heads.

A third, though somewhat more hybrid class of minstrel is the *barwa*. Prior to the British supremacy the *barwas* were primarily witch-finders and consequently a great power in the land. With the extension of law and order, however, their employment for this purpose has almost entirely ceased, and they have evolved into medicine men, and are called in to shriek their incantations at the bedhead of a suffering Bhil. The *barwas* are not a separate class, and any Bhil who feels the avocation innate in him and learns sufficient of the ancient songs may exercise the profession to its fullest extent.

TRADITIONS.

The Bhils possess no written records. It seems probable that their language was originally of the Munda stock, but at the present

time, as Dr. Grierson has noted ("Census of India, 1901") the dialect they speak is marked by a tendency to approximate closely to the local Aryan dialects in their neighbourhood; thus, on the western side, Gujerati, and on the eastern side, the Malwi dialect of Hindi have been largely absorbed, and the same applies to the southern districts, where the Khandeshi dialect has made itself felt. In spite, however, of this absence of uniformity and of a written tongue, the minstrels have maintained a large body of tradition. This is handed down by them from mouth to mouth. In addition there are the innumerable household songs, sung by women on family occasions which I have already mentioned. The minstrels go about in parties of five or six, each with a musical instrument. The leader recites a line or two of the song, which is repeated in chorus by the remainder until he starts a fresh line, which is again repeated, and so on through the whole story. In this way the song is learnt not only by his assistants, but also by the audience to a certain extent, and they readily join in the repetitions.

In a collection of these songs that I have made there are epic accounts of raids against the great Puar rulers of Malwa (A.D. 800 circ.) of similar contests with the later Mohammedan power, the Rajput chiefs of Udaipur, and so on; also quasi-religious stories based on the Puranic traditions.

One song that I heard had reference to an event which occurred twenty-three years ago, when the Bhils in the Ali Rajpur State rose against the Durbar, and the British authorities had to intervene to restore order. The author of the rebellion was one Jit Singh, a thakur of the State, who was discontented at the selection by the Government of India of Waje Singh, for the chieftaincy of Ali Rajpur. Jit Singh found ready allies in the turbulent Mekrani colony of Ali Rajpur, but probably nothing serious would have happened if general discontent had not at that time also existed amongst the Bhils, who formed ninety per cent. or more of the population. The chief was a minor, and the Diwan being incompetent, all power fell into the hands of his deputy, a man totally unfitted for his position. Owing to the neglect and carelessness of the higher officials, corruption and extortion extended to their subordinates. In order to make good a falling revenue, a number of small taxes were imposed on trivial articles. Land assessments were neither justly fixed, nor justly collected, and the headmen or patels, who, for several years, had not received their cash payments (*hakis*), were called upon to make good deficiencies of land revenue due to emigration. Finally, the *kallals*, or liquor contractors, were able, owing to the absence of supervision from headquarters, to encroach on the immemorial rights of the Bhils in the mohwa produce, thereby spreading discontent through all classes of the population. With the intervention, however, of the British authorities, the rebellion was rapidly quashed, and the leader of the Bhils — Chitu Patel — was eventually captured, and transported to the Andaman Islands, where he died. Such was the origin of the song which I heard sung at a dance a few years ago. The song compared the foolish patel, who led the rebels, to an ant who tried to walk with women's anklets on his feet, and the whole story of his temporary success against the local power, and his final destruction was most graphically and truly narrated. In this case the story had not passed into the hands of the professional bards, but was being chanted at a dance by a man whose father had taken part in the rebellion.

Future of the Race.

I have endeavoured to give, though I fear most imperfectly, an idea of this most interesting and attractive race. Much more might be written of their peculiar habits and customs, especially in regard to religious observances. The question of their future is also one of much interest, for though the mortality amongst them was very heavy during the recent famine years, they are in normal times a prolific race. Among the influences that are being brought to bear upon their future, are not only Hinduism and Mohammedanism, but also Christianity; and more than one flourishing mission exists in the Bhil country, where by force of example a certain number of these wild people are being induced to turn to steadier and more sober habits of life. Again, the standard of administration in the Native States in which they principally dwell is continually improving, and this also must inevitably react on them. Already their traditional rights over the forests, with the indiscriminate destruction which such rights brought with them, have been much curtailed, and it seems to me now largely a question of time that with sympathetic treatment they should gradually develop into a more settled community, possibly very largely Christian in its religion.

Eighty years ago, Sir John Malcolm when inaugurating the British supremacy in Central

India justly regarded them as a serious danger to the peace of the neighbouring territories, and he very clearly laid down the duties that lay on political officers in Native States to obviate this danger as far as possible by gaining their confidence, in ensuring them just treatment at the hands of the various Durbars. In the neighbouring British district of Khandesh, Sir James Outram's work in this connection is almost a matter of common knowledge. When this large area came into our hands in 1818, "murder and rapine stalked openly and unrestrainedly through the land." Fifty notorious leaders infested this once flourishing "garden of the West," and their every command was implicitly obeyed by upwards of 5,000 ruthless followers, whose sole occupation was pillage and robbery, and whose subsistence depended entirely on the fruits of their unlawful spoil. Smarting also under the repeatedly broken pledges of the former native government, and rendered savage from the wholesale slaughter of their families and relatives, the Bhils were more than usually suspicious of a Government of foreigners, and less than ever inclined to submit to the bonds of order and restraint.* The Satpura and Satmala ranges were infested with large bodies of warlike and disaffected men, and so insecure was the general condition of the lowlands that cultivators refused in many cases to accept the Government advances of grain for seed (*takavi*) on the ground that the crops, when ripe, would probably not fall to them but to the marauding Bhils.

For seven years every effort was made, principally by repressive measures, to induce a better order of things, but it was not till 1825 when Outram, then a Lieutenant, was appointed by Mountstuart Elphinstone, the Governor of Bombay, to carry out a definite policy of reclamation rather than extermination that any real reform or progress was initiated. Then, however, the progress was rapid. By gaining the confidence of the leading Naiks and commencing with a nucleus of nine men, he laid the foundations of the Khandesh Bhil corps, with which he subjugated and pacified the whole district. In April, 1827, he was able to report "that the peace of the country (South Khandesh) is restored." His Bhil corps was then 600 strong, and in the following year the Collector of the District reported to Government that for the first time in 20 years, the country had enjoyed six months of uninterrupted repose. In 1829 he advised the opening of a school for the children of his Bhil soldiers. In 1830-32 his operations were extended to the mountainous forest tracks along the northern borders of the district with the result that when he left Khandesh in 1835 there was general peace throughout the whole area, a peace which except in times of famine, or when broken by occasional exploits on the part of individual outlaws has since been maintained.*

It is natural in the Native States, where our influence must be exercised more or less indirectly, that progress should be less rapid than in a purely British district, such as Khandesh. But here, also, the instructions of Sir John Malcolm, and the traditions of Outram have had their effect, and though at the present time the Bhils are probably much more numerous in these States than they were then, and though they are still an extremely backward race, they are no longer a general source of danger, and certainly our influence amongst them is altogether paramount and their confidence in our good faith almost, if not wholly, unlimited.

LIST OF LANTERN SLIDES.

1. Bhils of the Vindhyan range. Malwa.
2. Bhils of aboriginal tribe.
3. Bhils showing method of fighting.
4. Bhils showing method of fighting, and also showing how the women give water to the wounded and are never hurt.
5. Bhils carrying off the wounded.
6. Bhils armed for a marauding expedition.
7. Bhil woman in full dress.
8. Bhil woman of Malwa.
9. Bhil musicians.
10. View in Bhil country with hamlet in distance.
11. Bhil dwelling.
12. Bhil dwelling, showing entrance.
13. Bhil dwelling, full view.
14. Bhil in native fighting costume.
15. A soldier of the Bhil Corps, Malwa.
16. Meywar Bhil Corps.
17. Officers and native officers, Malwa Bhil Corps.

Colonel E. D. F. Bignell (late Commandant Meywar Bhil Corps and Political Superintendent, Hilly Tracts, Meywar) kindly lent some of the photographs illustrating the paper and contributed the following notes :—

* Captain Douglas Graham's memoir.

* *Cf.* Goldsmid's "Life of James Outram," vol. i., pp. 51, *et seq.*

If a Bhil life is taken by a Bhil, he and the whole of the male members of his family, and his male relations are held responsible unless they pay the blood money, which they rarely do unless a British officer forcibly makes them. If not paid retaliation begins. A member of the killer's family is patiently tracked till he is caught off his guard, and, if possible, shot with a new arrow, highly ornamented and especially made for the purpose. A very shrill cry (*kilki*) is then given to inform the world in general that a blood feud has advanced another step, and the killer makes himself scarce, as it is now the turn of his family to lose a life. I have an arrow which was used in a blood feud with fatal results, and the tale of that blood feud will give you more information than pages of generalities. A Bhil in the Khotra district of Meywar woke up one night to find another Bhil trying to burgle his plough cattle. The burglar, when disturbed, let fly an arrow and decamped. The owner, enraged at this act, sent an arrow after the retreating figure, which hit and killed the man on the spot. The next day the dead man's relatives sent to say that as their man was killed when flying and not when fighting they demanded blood-money, or they would proclaim the *ver* or blood feud. The money was refused and the feud proclaimed. The man was a lonely individual, his entire family circle consisting of himself, his wife and two sons, aged four and two. Hence, for the time being, the feud could only go on with him, as, according to Bhil custom, until his sons grew up and married they were not liable. The man had several narrow escapes, and then died of cholera. Years passed, and the sons grew up till the eldest was eighteen, when he took unto himself a wife. The marriage ceremony lasted two days, and on the third he took her to his home, arriving late in the evening. He and his wife sat down by the fire, which was blazing outside the hut, whilst the mother sat in the doorway preparing the evening meal; suddenly the man pitched head foremost into the fire, scattering the sparks far and wide. His mother and wife fled shrieking, thinking a tiger had got him; but out of the surrounding darkness came the fatal "Kilki!" and they knew that the blood feud had claimed another victim. The corpse was brought in to me, and I found a new and very ornamented arrow had transfixed him, the feathers protruding from his left shoulder and the head from beneath his right ribs; death must have been instantaneous. I never could trace the actual murderer, but I got hold of the family, and forced them to go before a *punchayet* and adjust their grievances with the remaining boy, thus ending the feud.

Whenever anything unusual occurs a Bhil at once sends for the witch-finder, who assembles all the inhabitants of the *pal* and holds his investigation. The cause of his being sent for may be numerous deaths in a particular family or in the village, continuous loss of cattle, or mysterious sickness, in fact anything the mind of the Bhil cannot grasp. The witch-finder seats all the people, male and female, in a semicircle, and divines by counting the number of beans he takes out of a bowl or the number of grains in an ear of barley, &c., the tribal drums making a hideous din all the time. Suddenly he darts forward, and passes round the semi-circle of terrified men and women; backwards and forwards he rushes, getting wilder and wilder in his gestures, till he makes a pounce at a cringing figure, and drags him or her to the front. The fate of the suspected one is sealed. Ropes are produced, and fastened to her ankles; she is taken to a tree on the outskirts of the village, reserved for such purposes, and slung head down from a lofty branch; a pad of ground red pepper is bound round her eyes, nose, and mouth; a fire of green wood is lighted below her, and a big stone is rolled forward, so that it is more than probable her head will strike against it. She is swung slowly backwards and forwards, while the witch-finder, who is kept supplied, by eager assistants, with green wood sticks heated in the fire, applies them to her back or any tender part, and implores her to confess her guilt. The victim is practically never allowed to escape; if by any chance she does not knock her brains out against the stone, a slash or two with a tulwar puts an end to her misery and her witchcraft. Her remains are then buried nine paces from the tree.

In all tribal fights the women supply the wounded with water, and it is a point of honour amongst the Bhils that under no circumstances may the women be injured. I have seen them moving through a perfect rain of arrows yet not a single girl was touched.

The Secretary of the Section read the following communication from Colonel C. E. YATE, C.S.I., C.M.G.:—"I much regret that an accident prevents my attendance at Captain Barnes's lecture to-morrow. I have perused the advanced proof of his paper with interest, and there is just one point that Captain Barnes has not dwelt upon and which I should like to notice, and that is, the fine material for useful soldiers that we have in the Bhils. My time was spent more amongst the Bhils of Meywar, Dungurpur, Banswara, and Pertabgarh in Rajputana, than amongst those of Jhabua and other States in Central India, which have been specially described by Captain Barnes, and I know more of the Meywar Bhil Corps than I do of the Malwa Bhil Corps; but I believe both corps to be much the same. The Bhils are born trackers and scouts, lithe, wiry, little men, capable of long distance marching, and thoroughly faithful and reliable. The Bhils were faithful to us to a man in the Mutiny, and would be equally faithful again in case of any disturbance in India. They are so to speak the Gurkhas of Central and Western India, and just as the Gurkhas of the North have their permanent cantonments in the hills, so do the Bhils require their permanent cantonments in their hills in the South. The Meywar Bhil Corps, for

instance, has its cantonment at Kherwara in the Meywar Bhil tracts, and so long as that cantonment is permanently guaranteed to them, the Bhils will enlist readily. I believe that a second Bhil corps could be raised in Kherwara in a month at any time, should we require it, and a right valuable reserve we have there; and one never knows when more men may not be wanted. Should the Bhil corps be de-localised, however, and sent elsewhere, and their own cantonment at Kherwara taken away from them, the Bhils would never enlist. But why should this be done? We give the Gurkas local cantonments, why should we not give the Bhils the same? I mention this, as there is a craze for de-localisation of all local corps in India at the present time, which, if put into effect as regards the Bhils, will result in the loss to us of the entire Bhil country as a recruiting ground. In war, the Bhil will go anywhere, if only he is guaranteed the return to his own local cantonment at the conclusion of the war. The one thing he dreads is, to be deprived of his local cantonment in the midst of his own native hills, and as long as he is permitted to serve there in peace time, he will remain for us a valuable and faithful asset in time of war."

DISCUSSION.

The CHAIRMAN said that the one question which presented itself to thoughtful minds in all discussions of Indian subjects, was how far the British nation and its agents in India were fulfilling their trust and faithfully discharging the national duty to its peoples. The two papers already read before the Society this season brought home to us the wide differences between the various peoples of India. What a contrast between the Mohammedan Empire-builders, dwellers in crowded cities, and worshippers of one God, and the Bhil dwellers in isolated huts buried in the seclusion of the forests and totemists. The Bhils were a fair representative of the large class grouped as animistic, numbering 8,576,000 souls, of whom only 975 had ever learnt or were learning to read English. Yet they had their rights as well as the other classes of the 293 million fellow-subjects of the King, who, between them, counted 1,125,000 literates in English. To the animistics, British Indian laws and institutions were as much the home in which they lived as they were to Hindus, Mohammedans, Sikhs, Buddhists and others; and those who took an interest in devising fresh laws and constructing new constitutions for India, must take count of the human wreckage which immigration and disorders had cast up on the mountain ranges and forests of India. Captain Barnes's paper on the Bhils was an immense advance in knowledge gained on the paper read by Sir George Birdwood, in 1868, for Mr. Gibson, before the Royal Asiatic Society of Bombay, and it was a credit to the great political department to which the writer belonged. For the political officers in India had never been content with just doing the work before them and drawing their very modest pay. They had studied the habits and minds of the people amongst whom they lived, interpreted records on brass and stones which even the Indian residents of the State could not understand, and contributed valuable articles to journals and more permanent literature upon men and matters of which little was known. Captain Barnes was walking according to the best traditions of his great service. Perhaps he might have told us that the name of Bhil was derived from a Dravidian Kanarese word *billa*, signifying "bow," and he had underestimated the population of bowmen by not including the Bhilalas some 145,000, who were the result of marriages with other races. His account of the natural truthfulness of the Bhils was a new experience. He (the Chairman) had always heard that the Bhils were absolutely truthful if they swore by Baba Deo or the Raja's Gadi, or other holy names recognised by the various tribes, but generally untruthful in ordinary intercourse. But be that as it may, all authorities agreed that they were a most interesting people, timid, superstitious, idle, and happy, as well as patient and courageous. Such a people ought to have a future before them, and there was no doubt of their affection and loyalty to the British officials who deserved and won their confidence. When the Poona Peshwa staked his sovereignty, in November, 1817, on a treacherous attack upon Elphinstone and lost all on the field of Kirki, dominion over the Bhils of Khandesh and Gujerat passed into British hands. They were then reputed to be the most unmanageable of human ruffians, enemies of society, incapable of discipline. The Brahman rulers of Western India had made them what they were, for they knew only one method of dealing with them—extermination and torture. In 1804, 7,000 Bhils were inveigled by Balaji Lakshaman, the Peshwah Governor to Kopargaon, and then thrown into wells and left to die there, wounded and maimed. Two years later Naroba organised a grant beat in the jungles, and in fifteen months he reported that he had massacred 15,000 of them. The most brutal tortures were inflicted upon those who were captured. No wonder then that those who survived cherished undying hatred ot the Poona Government, and ravaged the villages in the plains whenever they could. No wonder that they disbelieved at first in the promises of British officers and would have no communications with them. But after a short period of reprisals and punishments, the British in 1825 resolved to try a new system. Outram, the Indian Bayard, was authorised to enrol a corps of the bowmen, and to establish colonies of them in convenient spots for agricultural operations. His first step was to catch some Bhils alive and red-handed, then he set free some of his prisoners, promising to release the rest if they would return with their families. The Bhils found the Englishman true to his word, and his next step was to trust himself alone in their company anp join them in the chase. After a while five Bhils

attached themselves to him, and on January 1st, 1826, 134 had joined his corps which presently increased to over 300 men willing to remain in barracks. In 1828 Giberne, the collector, reported that for six months no attacks had been made by Bhils on the province. Gradually the tribesman settled down to agriculture, received loans of money, and found the industry fairly remunerative. At times some sudden fancy or inexplicable movement has caused some of them to revert to the old nature, as when in 1882, a party rebelled against the authorities in Pol, and attacked the carriage of the Political Agent on the Ahmedabad Idar road. But the temporary detachment of two companies of a native regiment was sufficient to restore order. More difficult has it been to attract them to relief works in times of famine when their superstitions have been stirred, and they have put their trust in their gods and totems rather than in the relieving officer. But still matters have advanced so far that the Bhil corps in Khandesh has been disbanded, and the special Bhil agencies are now threatened with extinction. It is believed that the Bhils have been reclaimed, and are fit to take their place as citizens of India, under the fostering care of the regular district officers, provided that suitable officers, fond of sport and favourably disposed towards the Bhils, are put over them—such as Ashburner and Propert (Raja) in the past, and others now in the service of Bombay. These measures for abolishing institutions, which have worked well, require careful watching. As to the future, more must be done by education, and by raising these animistic tribes to a higher conception of God and religion. In this, missionaries are taking their part, and a wide field for conversion is open to Hindus, Mohammedans, and Christians. There is much in the Bhil character that appeals to humanitarian sentiments, whether we look at their state of ignorance, or the trials they have endured in the past. Captain Barnes's sympathetic paper shows that our officers try at least to understand these bowmen, and we may rest assured that the interests of eight and a-half million animistic subjects of His Majesty will not be forgotten by a paternal Government in shaping the future development of Indian laws and institutions.

Colonel T. H. HENDLEY, C.I.E., remarked that he was particularly interested in the paper, because thirty-six years ago he was the Medical Officer of the Meywar Bhil Corps, the head-quarters of which were at Kherwara. In 1875 he read before the Bengal Asiatic Society a paper on the Meywar Bhils, and he had, therefore, been exceedingly pleased to hear the extremely accurate account given by Captain Barnes of the Khandesh and Malwa Bhils. Although the paper referred particularly to Malwa and Khandesh, many of the illustrations were taken from the Kherwara Bhils. With regard to the ethnology of the people, he had measured the skulls and the principal bones of more than a hundred men in the Meywar Bhil Corps. Measurements were carefully made and compared with those of other tribes, bu he did not recollect that any very definite information was obtained. The head of the Bhils, however, was broad instead of being long like that of an ordinary Hindu of the plains. Another interesting point was the language of the people, which had been particularly studied by the late Rev. Mr. Thompson, of the Church Missionary Society, Meywar, in the Hilly Tracts. Mr. Thompson came to very much the same conclusion as himself, namely, that the language of the Bhils varied in accordance with the tribes in the immediate neighbourhood. There were certain elements in the language which were not of Sanskritic origin. With regard to the question of the origin of the Bhils, the author had made reference to the Bhils having been derived from certain rubbings which took place on the dead body of the Raja of the Earth. If he (Colonel Hendley) had known that views were to have been shown, he would have brought with him a lantern slide which represented the artist's idea of the creation of the Bhils. It represented the corpse of King Venu being rubbed by the sages, and his vices coming out of his leg in the form of a Bhil, very much of the kind described in the paper, while his virtues came out of his hand in the shape of a fully-armed Rajput. The author had referred to the truthfulness of the Bhils, and he remembered stating in his own paper that truth was very characteristic of the race. The fact was probably due to the simpleness of the people. Before the Meywar Bhil Corps was established in 1841, and in the very early days of the corps, the Bhil, when he was questioned, always spoke the truth at regimental enquiries. But, unfortunately, he had learned to lie with the advent of Brahman native officers who had taught him his drill. With regard to the women, they were no doubt very much the masters of the situation, but he was able to narrate a curious story which, he was sorry to say, illustrated the want of faith in Bhil women. One of the men in his corps, who was acting as a beater to a shooting party, was shot in one eye by a small pellet, the sight being completely destroyed. On the man coming to Kherwara, he (Col. Hendley) suggested that the only way to save his other eye was to remove the damaged one, but the man replied that his wives, of whom he had seven, stated that they would not support or remain with a one-eyed man, because a one-eyed man was generally considered unlucky all over India. They promised, however, that if he lost the other eye as well, that they would support and remain with him. The man did eventually lose his other eye, whereupon all his wives immediately deserted him! Reference had also been made to the brass ornaments worn by the Bhil women. He had often seen Bhil women having brass ornaments fitted on their legs by a blacksmith, one of the most characteristic ornaments being W-shaped. That particular shaped ornament was only worn by married women, and it was removed from them when they became widows.

It was a rather curious fact that, among the Bhils, there were a good many old maids, which was rather different from the state of affairs in the Hindu community. Many other customs were mentioned in the paper, which showed, he thought, that the Malwa Bhils and the Western Indian Bhils were more Hinduised than the Rajputana Bhils. The author had also made reference to horses, in connection with which a rather curious religious idea was associated. On the tops of the hills, little cairns were frequently to be seen full of clay horses, with a large opening at their backs, the idea being that when the Bhil died, his spirit went into the horse, and ascended so far on the road to heaven. Heaven was considered to be within the compass of twenty horses' journey or so; thus if the Bhil put up twenty horses during his lifetime he was well on the road to heaven. That was not only a belief in the Meywar tracts, where his own observations were made, but it was also noticed in other parts of India. A paper was read some time ago in which the author referred to a similar collection of horses in the neighbourhood of the battlefield of Plassy and in other parts of Bengal. The marriage customs narrated by the author were very much more Hinduised than they were in his (the speaker's) part of the world, where it was only necessary for an old man of the tribe, or an old fakir, to unite the couple, and after certain feasts and other ceremonies the contract was completed. The remarks that had been made on the subject of cremation were perfectly correct; in fact, the one point which struck him about the paper was its extreme accuracy on all points on which he had any knowledge. What the Chairman had said with regard to the disorderly state of the Bhils was no doubt perfectly true, but much of it was the result of oppression. Mr. Thompson in his book gave a long account of the cruel way in which the Mahrattas persecuted the Bhils in the southern parts of Rajputana. There was a mixture of cruelty and kindness, even in the treatment of the Rajput overlords, so that one of the most beneficent things the British Government ever did was to establish local regiments. The wild spirits among the Bhils very soon enlisted in the Bhil corps, and in his own time there were generally two or three hundred "expectants," as they were called, who were waiting in the hope that they would shortly be taken into the corps. There was one difficulty connected with such local regiments, namely, that the Bhil would not be likely to serve except under his own officers whom he trusted, nor would he be prevailed upon to go a long distance from home. They had a very curious custom that the men kept their wives and families in their own villages, and when they obtained two or three days' leave they travelled sometimes as much as thirty or forty miles to join their families in their particular villages; so that if the head-quarters of the regiment were a long distance off, it would be impossible for the men to do that. With regard to the question of the Christianising of the people, he remembered that a Hindu reformer rose up in Meywar some 35 or 40 years ago, who had a great influence over the Bhils, and when he died he foretold that the Bhils would change their religion, saying, "On the spot where we are now sitting a place of worship of a new religion will be erected. You will worship the God of this religion with a new name. It will take place 'When a certain tank near by shall be repaired.'" This tank was repaired during the famine of 1902. That place was now the centre of a very large Christian mission, founded by Mr. Thompson, in the schools of which 3,500 children were being educated, and it was very interesting to note that the present clergyman of the mission bore the honoured name of Outram. In conclusion, he had no doubt that many Anglo-Indians would find that their knowledge of a very interesting people had been greatly enlarged through Captain Barnes's excellent paper.

Mr. IAN MALCOLM said he would not like to leave the meeting without saying how grateful he was to the author for the very admirable paper he had given upon a subject on which a good many people were still in need of information. He could not help feeling that the Chairman struck the right note when he referred to the paper as being not only an important one with regard to the Bhils, but an example of the innumerable variety of tribes in India which were ruled in the name of Great Britain. Sir William Lee-Warner had struck in his (the speaker's) heart a responsive chord in the tribute he paid to those who ruled over such a variety of races, and he should never lose an opportunity of paying his highest tribute of admiration and respect to the members of the Indian Civil Service, without whose magnificent services, day by day, and night by night, he did not think British rule in India could continue very long. The one or two remarks he desired to make were entirely complimentary in character and not at all critical. The Bhils with whom he had become acquainted in the course of travelling through India were the Rajput Bhils; and he entirely agreed with what had been said about their bravery and courage, and largely with what had been said about their truthfulness. The last time he saw much of them was during the frightful famine of 1901; and, animistic and totemistic though they were, the way in which the Bhils of Rajputana bore their privations was beyond all praise. He was glad to join in a tribute paid to their bravery during the famine. Reference had been made in the paper to the fact that gaiety was one of the characteristics of the people. He remembered when he was in Udaipur in the previous year having a conversation with some Banias, and a lady who was present said she had never seen a Bhil, and would like to do so in order to get a photograph. Accordingly a Bhil was brought from a neighbouring garden with his bow and arrow. A mischievous idea struck one of the party, who said to the Bhil, "Show us what you would do to the Bania if you met him on a dark evening." Before one could say "knife," the

Bhil had tied his puggaree across his face so as not to be recognised, had butted the poor Bania in the pit of the stomach, knocked him down, taken his bag and his turban, and getting behind him, had drawn a bead with his bow on the prostrate Bania. That was a Bhil's idea of a joke. When he was staying at Mayo College last winter, he saw one of the young princes who ruled over a large number of Bhils, and he showed him one volume that he had already written in excellent English of the history of the Bhils, which he was now preparing and hoped to have ready for publication by the time he was twenty-one. Personally, he thought it would be a very valuable book, and those people who knew anything about the Bhils would probably be the first to pay their tribute to it. He thought it was a marvellous thing that a boy of 17, who was at school at the present time in India, could write a book which any author in England would be proud to be able to write. The chapters written by the prince were appearing three times a year in the *Mayo College Magazine*, and if any of those present ever had the opportunity of reading them he was sure they would agree with him as to the excellent manner in which they were written.

On the motion of the CHAIRMAN, a very hearty vote of thanks was accorded to Captain Barnes for his interesting paper.

Colonel DUNCAN PITCHER writes:—As time would not admit of my joining in the discussion which followed the reading of Captain Barnes's admirable paper I beg to submit a few remarks for inclusion in the *Journal* should space permit. The cost of the Malwa Bhil Corps is borne, practically, by the following Native States—Gwalior, Dewas, Dhar, Jaora, Jhabua, Barwani, and Ali Rajpur, who between them pay about Rs. 4,15,585 per annum, the British Government contributing only Rs. 9,828 per annum. Holkar formerly contributed but compounded a few years ago by a payment in cash. Now that Sirdarpur has been abandoned as a station and the corps transferred to Imperial service at Indore with detachments at distant Nowgong and Sutna in Bundelkhand, while the Native States in question are deprived of the security from Bhil aggression and unrest which their contributions were arranged to insure, those contributions should surely be remitted else our good faith may run risk of being doubted. When a proposal was made by the Supreme Government to Sir Arthur Wellesley which, to his mind, involved a breach of faith towards the vanquished Dowlat Rao Sindia, Sir Arthur replied in so many words that he would rather our possessions were lost than our reputation for good faith. A friend who witnessed the final march out of the Bhil Corps from Sirdarpur describes the scene as a most trying one from the crowds of wailing women and children who followed for some two miles and had at last to be forcibly driven away. Desertions had begun and are likely to continue.

NINTH ORDINARY MEETING.

Wednesday, February 6th, 1907; Professor HALFORD JOHN MACKINDER, M.A., Director of the London School of Economics and Political Science, in the chair.

The following candidates were proposed for election as members of the Society:—

Clarke, Allen H., 74, Inverness-terrace, W.
King, Captain Alexander E., R.A., Ordnance Office, Citadel, Cairo, Egypt.
Mansell, Major John Herbert, R.A., 108, Shooters-hill-road, Blackheath, S.E.
Prevatt, Francis C., 106, Henry-street, Port of Spain, Trinidad, British West Indies.
Tanner, William Hugh, Public Works Department, Mombasa, British East Africa.
Weston, Robert Ogilvy, M.Inst.M.M.,A.M.I.Mech.E., The Globe and Phœnix Gold Mining Company, Limited, Que Que, Rhodesia, South Africa.
Yate, Colonel Charles Edward, C.S.I., C.M.G., 17, Prince of Wales's-terrace, W.

The following candidates were balloted for and duly elected members of the Society:—

Bancroft, Augustus Charles, J.P., F.S.I., Stokes-hall, Plantain-garden River P.O., Jamaica, British West Indies.
Cooper, Hon. Francis Alfred, C.M.G., M.Inst.C.E., Director of Public Works, Colombo, Ceylon.

The CHAIRMAN, in introducing the reader of the paper, said that the subject to be discussed was one which was daily occupying more attention, householders at the present moment being particularly interested in one of its aspects; indeed, he occasionally thought that some of the aims of Socialists would be accomplished through insurance without abandoning the individualist basis of society. Everyone would agree that it was of the greatest importance that the whole profession connected with insurance should be such as could be trusted, not only for their skill, experience and knowledge, but also their probity. The education of gentlemen belonging to the actuarial profession was being much discussed at the present time, and it was therefore a matter of great interest that so distinguished an ornament of the profession as Mr. Young was to read a paper on a very wide subject connected with it.

The paper read was—

THE PRINCIPLES AND PRACTICE OF INSURANCE AND THEIR MODERN DEVELOPMENTS.

By Thomas Emley Young, B.A.,
Past President of the Institute of Actuaries, and Past Chairman of the Life Offices Association.

"On all great subjects," remarked John Stuart Mill, "much remains to be said;" and Coleridge has inspiringly pointed out* that the redemption of inert truths to regenerated vigour is won by their incarnation into forms directly related to man's personal and social circumstances and needs. I am encouraged by these sayings in my attempt to confer some freshness upon the familiar subject of insurance, by combining its theoretical aspect with its practical agency in our social and commercial system.

You will remember one of the striking antitheta of Lord Bacon, "Fama veluti fluvius levia attollit, solida mergit."† Like most similes derived from physical Nature, its importation into the domain of human activity is of precarious value; and, as in all epigrams, the completeness of truth is sacrificed to brevity and symmetry of literary form. Still, the metaphor is not useless, and history frequently testifies to its validity. Our subject affords an exemplification. We possess the story from Aristotle of a financial transaction in olives, successfully effected by the founder of the earliest Greek school of mathematics, Thales,‡ which formed the first known commercial "corner" in business, while the subject of deeper human import, insurance, can point not even to a legendary example of its primitive forms. It is true that Mr. W. E. H. Lecky, in his "History of European Morals,"§ informs us that among both the Greeks and Romans, mutual "insurance" societies existed which undertook to provide for their sick and infirm members, and he cites Pliny's Epistles as his authority. If you care to refer to the Letters, numbered xciii. and xciv., which passed between the Emperor Trajan and his Consul, Pliny,‖ you will discover that the society, for whose establishment Pliny pleaded on behalf of the city of Amisius, was simply a charitable institution for the support of the indigent. And the learned Casaubon aids us here by showing (in a citation from an ancient commentator) that, in Athens and other cities in Greece, fraternities were founded where monthly contributions were paid into a common chest, from which pecuniary help was granted to necessitous members on condition that, on the advent of more propitious fortunes, the moneys so advanced should be refunded. Mr. Lecky, accordingly, is inaccurate in the employment of the term "insurance" as applied to ancient history. Societies of this nature were merely related to the scheme of insurance so far as insurance is founded upon that feeling of mutual co-operation which humanity and the requirements of civilisation suggest and enjoin. I am naturally referring here to that crude form of insurance which involves the mere mechanical sufficiency of numbers to produce average and balancing results even without the element of interest, and, of course, without the introduction of the systematised principles of probabilities: in other words, the form of insurance which common sense and general observation of the stability of large numbers would indicate. For the organised system of insurance, as we properly conceive it, only became practicable when the calculus of probabilities had been created. And as the illustrious Laplace observed, it forms a most memorable and instructive fact that a science,—that of probabilities,—begun as a mere computation of chances connected with the events of gambling hazards, should so expand in its manifold amplitude of practical serviceableness that it has become, not simply ancillary to mathematico-physical problems but the valid foundation of social organisations of the profoundest import and scope. A moment's reflection upon the range of marine insurance, for example, will suffice to show the restricted area to which commerce with its civilising functions would have been confined if this doctrine of the constancy of recurrent results which extensive numbers involve, based upon the universal principle of continuity in Nature, had never been evolved and expressed in numerical forms. It has always impressed me with wonder that the subtle mathematical genius of the Greek which devised the Method of Exhaustions (exemplified in Euclid, Book XII., Proposition 2, and essentially embodying the principle of Newton's Method of Limits and the Calculus of Leibniz) failed to discover the science of Probabilities. Was it that the

‖ Edition by W. Melmoth (1805); Vol. ii., Book x.

conception of a universal Fate obstructed the adventure? For they were intimately acquainted with games of chance, and their dice-playing with ἀστράγαλοι and κύβοι* frequently reduced the gamblers to ruin. It was reserved, however, for the versatile Pascal, in 1654, to establish the principles of the theory of probabilities by solving a problem submitted by a gamester relating to the proportionate division of stakes where two players of equal skill, after each had gained a specified number of scores, decide to abandon the game. That problem of Points—as it is termed in the history of mathematics—furnished the origin of the principles on which the practical execution of insurance is effected. For a time the theory was restricted in its application to regulate the stakes and expectations of games, but Jacob (or, as he is usually called, James) Bernouilli appears to have been the first to suggest that the phenomena of the physical and moral universe, exhibiting though they do, anomalies and irregularities when surveyed in fractions, reveal, when a spacious range of view is adopted, so marked a uniformity of coincidence and succession as to render them amenable to numerical estimation. In his "Ars Conjectandi"—arrested in completion by his death and published as a fragment in 1713—he enunciated the important Proposition of Large Numbers† (as it was appropriately named by the mathematician, Poisson). As this theorem constitutes the main foundation of systematic insurance, a brief explanation of its nature and significance may be offered. If a series of trials be instituted respecting any event which must either happen or fail at each occurrence, the probability continually increases, with the extension of the trials, that the proportion of occurrences of the event in a specified mode to the total number of trials will be equal to the ratio shown at a single trial. A familiar illustration will be useful. If a justly-balanced coin be spun in the air, the chance of head appearing in a single trial is obviously one-half; a dictum of commonsense where no *à priori* tendency or preponderance in favour of head or tail exists. This fraction expresses the ratio of the favourable event to the sum of the possible events. Now it is found that as the trials are augmented, precisely the same ratio tends to prevail, and as this tendency increases with the extension of the trials, it holds exactly in the limit when the trials proceed to infinity. Thus, the naturalist, Buffon, obtained 2,048 heads in 4,040 trials, or 50·69 per cent.; another experiment showed 2,048 heads in 4,092 instances, or 50·05 per cent.; and Mr. Karl Pearson has recently recorded in another set of 12,000 trials 49·84 per cent. of heads, and in an extended set of 24,000 trials 49·95 per cent. Thus, the more enlarged be the area of the experiments, the more closely does the total ratio approximate to the result exhibited by a single trial, of 50 per cent., or one-half.

What does this signify in connection with the application of the theory of probabilities to life assurance? The probabilities of life and death obviously are inapplicable, from the nature of the case, to *individuals* who in this science can only be regarded as constituents of a *mass*. Suppose then that we select an adequate number of boys of the age of 10, and find that out of 2,000, 1,929 survive to the age of 20; we are confident that practically the same ratio will exist when the numbers at the younger age amount to 10,000, and closer still if we survey the whole of the children of 10 in a century, assuming that the social condition and other circumstances reasonably correspond. Hence, our fundamental mode of operation may be exhibited in an example. A table of mortality shows, out of a stated number born, the numbers who survive to each successive age until all have become extinct, and the difference between the number so living at any one age and the number living at the next higher age furnishes obviously the number who have died in that particular year of age. The number existing at age 25, extracted from the table of mortality which now forms the standard for assurance companies (with the numbers proportionately modified for convenience of treatment), is 3,146, out of a certain larger number born; the number living at age 26 is 3,131, so that 15 have died during the year. The chance of death, accordingly, in that year, is measured by the number of cases favourable to death, or 15, divided by the number of 3,146 who, starting at age 25, must either live or die during the ensuing year; the chance, therefore, is about five in 1,000. So that if a company assures a life for one year at age 25 for £1,000, the value of the risk it incurs, and, therefore, the price to be paid by the assured, is the sum to be received multiplied by the probability of receiving it, *i.e.*, by

* Becker's Charicles, 6th Scene, Excursus iii.

† Bernouilli himself stated that the solution of this theorem occupied his mind for 20 years, and certainly that prolonged time was worthily expended in devising this efficient instrument by means of which the vast social scheme of insurance has been securely erected.

the chance of death, or £1,000 × ·005, or about £5. But as the company will obtain one year's interest upon this price the cost to the policy-holder must be reduced by the discount for one year, usually assessed at 3 per cent. The present price for the company's risk of payment during the second year, *i.e.*, from age 26 to 27, is obtained by multiplying the chance of the life aged 25 surviving to age 26 into the chance of his dying in the ensuing year, discounted again for two years, since in the theory of assurance the sum assured is payable at the end of the year of death or, on the average, six months after the date of death. This process being repeated for every separate year to the extreme term of existence furnished by the table of observations; and the several individual values being summed, the total constitutes the single premium for the risk attending an assurance for the entire period of life. When that premium is increased by additions representing the contribution to expenses of management, a provision for possible adverse fluctuations of experience, remuneration for the protection of the proprietary capital (where that exists), and, in respect of participating policies, by an assessment to the profits in which (accumulated at interest) they are successively to share, we obtain the single premium charged to the public. This is readily converted into a precisely equivalent annual amount.

Here again let me interpose a caution to which I have already referred, and which some of our ablest mathematical writers have, through carelessness of diction, failed to observe. We cannot, from the necessity of the case, calculate the chances of life and death in *individual* instances; the probabilities I have explained cannot express the probabilities or expectations of a *particular* person surviving the successive ages, or dying during their currency; but our propositions, when related to individuals, should thus be interpreted,—that if we assume a sufficient number of persons at the age of 25, *e.g.*, then the chance of attaining the ensuing age is 995 to 1,000. We deal exclusively and consistently with the conception of large numbers involved in Bernouilli's theorem, and apply our calculations to a mass and not to the unit. It is true that, when effecting a life policy, an individual contract is completed, but the premium charged is deduced from the experience of extensive numbers of persons as an average result, so that the quoted premium does not measure the risk attaching to the assurance of an *individual* policy-holder of the stated age, but the risk appertaining to a number of policy-holders of that age among whom the individual in question is included. The consequence is that, as the essential basis and implication of the scheme, those who reach the higher ages necessarily, by their more numerous payments of premiums, contribute in excess to the discharge of the earlier claims in connection with which few premiums have been received, and thus the conception of an average is realised.

The guiding principles affecting the statistical foundation of life assurance—and the remark obviously applies to other descriptions of insurance—are (1) the sufficiency of numbers, and (2) a congruity of nature in the materials which constitute the data—in life assurance, *e.g.*, this congruity will include racial, social, and physical conditions. The first criterion is involved, as I have stated, in the conception on which Bernouilli's theorem is based as the necessary condition of the stability of results.* In respect of the second principle, Dr. Whewell† has illustrated the requisition in science of the Appropriateness of the Ideas which are to be applied to each department of investigation; and it is of deep interest to observe that our illustrious countryman, Dr. Edmund Halley, the first predictor of the return of a comet within our skies, the first to suggest the employment of observations of the transit of Venus in the determination of the sun's distance from the earth, and, crown of all, the efficient cause of the world's illumination by Newton's "Principia," was also the pioneer‡ in proposing that the appropriate ideas in the tabulation of numbers as the basis of a table of

* I regret to remark that I have known instances of the violation of this imperative principle by actuaries themselves. I have seen a valuation of the liabilities of a society where the total number of members was less than 30! In other words, the application to this utterly inadequate number, of functions of value deduced from a mass of observations is entirely delusive, and the results obtained and judgment expressed absolutely worthless. We perceive this grave absurdity in other forms of statistics—which I have elsewhere described as the fallacy of percentages. It is stated, *e.g.*, that 50 per cent. of the persons attacked by a particular disease have died; but any alarm or significance will be dissipated when we remember that one death out of two attacks constitutes equally a percentage of 50 as 500 deaths resulting from 1,000 attacks. Hence we derive the practical maxim that percentages should never be accepted as conclusive or material until the aggregate number out of which those percentages are constructed, have been ascertained and weighed.

† Nov. Org. Renov. Book II., chap. ii., section iv.

‡ "Phil. Trans.," Vol. xvii.

mortality consisted of fundamental similarity of data,* and the discrimination (in the premiums) of age. The absence of conformity would be manifest if we promiscuously combined into one table of mortality the experience of different races with their discrepant conditions of life, and varying ancestral types of heredity affecting the chances of longevity; or if, in a table intended for the assurance of male lives, were incorporated the experience of females, whose lighter mortality would thus depress the premiums below their properly relevant level; or, again, in the inclusion of the records of annuitants in the formation of a standard designed for the estimation of assured lives alone. Assurance companies have, for a considerable period, and never so exhaustively as at the present time, precisely observed this condition of consistency by the adoption of a table of mortality deduced exclusively from the experience of lives previously assured.

It is obvious that the records of the past constitute the most appropriate measure of the future as regards the nature and indications of the data to be employed.† I may here interpose a specific observation upon this congruity of materials. Regarded throughout the entire duration of life, females exhibit a higher vitality than that of males; and one company (still in existence) thence determined that it was unjust to demand identical assurance premiums from the two sexes. Females were, accordingly, admitted upon more favourable terms than males; but experience of their mortality speedily and decisively compelled the abandonment of the experiment. For it has been found that, during the period of child-bearing, the mortality of women exceeds that of men, but, after the age of 50, the vitality of women so markedly surpasses that of men that the superiority cancels, so to speak, the enhanced mortality of women during the stage I have named, and confers upon them, in the complete duration of life, an augmented longevity. Now as assurances upon female lives as upon males are effected during this more dangerous prior period, the foresight of the actuary who suggested this innovation thus received a signal practical rebuke. An important example of incongruity of data and its financial results may be cited from our national history. In 1819, Mr. John Finlaison, the Government actuary, reported to the Chancellor of the Exchequer, Mr. Vansittart, that the scheme of granting annuities for the purpose of creating public funds, on the basis of the Northampton Table of Mortality, involved the national exchequer in a serious annual loss. The Northampton Table had been constructed in 1771 from the mortality-experience of the inhabitants of that town, and when the practice of raising loans by the issue of life annuities was adopted by the Government in 1808, an actuary, Mr. William Morgan, was consulted, and prepared rates of annuity on the basis of that table. Its peculiarity consists, speaking generally, in its heavy rate of mortality and its consequent inapplicability to female life, and since annuities are mainly purchased on the lives of selected female nominees on account of their superior prospects of longevity, and purchased, moreover, after their dangerous period of life has been survived, this incongruity of basis resulted, in the 11 years from 1808 to 1819, in an aggregate loss to the country of £2,000,000 of money.

An essential principle of life assurance is the regulation of the premium according to the probabilities of life at each specific age. At age 25, the chance of dying within the space of the ensuing year is about 5 in 1,000, while at age 55 the corresponding chance is about 20 in 1,000, or four-fold; the variation consequently in the values of the risks demands a relevant discrimination in the prices required for the assurance of those risks. An ancient and honourable society—the "Amicable" (established by charter in 1706, and merged into the "Norwich Union" after

* If I had not more strictly confined this lecture to the history of assurance, and its associated science, as dependent upon British enterprise and research, I should have cited the conception of congruity exemplified by Deparcieux, when, in 1746, he constructed a table as an instrument of measurement of the mortality of annuitants, from the experience of the deaths which had actually occurred in this special class among the tontine nominees in France. And also the similar directing notion of the Grand Pensionary of Holland, John de Wit, who, in 1671, presented a report to the States-General of Holland, in connection with their decision to raise public funds by the issue of annuities, in which he based his statistical and monetary suggestions upon the congruent foundation of the course of mortality ascertained to prevail among the grantees of annuities already purchased in Holland from the Government.

† Although a table of mortality expressive of the experience of an adequate numbet of assured lives in general is justly and appropriately adopted in calculating the value of the liabilities of any particular company of reasonably similar conditions, it is clear that, since companies differ to some extent between themselves in respect of the distinctive character of their experience, the theoretically accurate plan, if this separate experience be sufficiently extensive, would be for each company to tabulate its individual records and utilise them as the basis of its computations and assessments. This course, however, though undoubtedly theoretically correct, is practically needless in consequence of the prevailing general identity of the several experiences on the whole.

an existence of 161 years) violated this essential condition by charging the same rate of premium at every age, and thus heavily oppressed the younger and more vigorous members for the inequitable benefit of those of advanced ages. The premium for the risk of death under a whole-life policy at the age of 25 is £1 10s. 6d. per cent. (assuming a basis of interest of 3 per cent.), while at 55 it amounts to £4 12s. 10d. per cent., or 204 per cent. in excess—an excess measuring the extent of injustice thus committed upon the younger lives. It was not until the "Equitable" (still in prosperous existence) was established in 1762 that the premiums were adjusted as direct functions of the several ages under the advice of an able mathematician, Mr. James Dodson.

In the practical computation of assurance premiums the amounts directly deduced from a table of mortality are simply sufficient to provide for the risk of death, and, as I have stated, are then augumented by the addition of a quantity (composed of a constant and a percentage), incongruously termed the "loading," for the purposes which I have already described.

And now we arrive at the consideration of a factor as essential as the rate of mortality, the force of compound interest, but I shall treat this subject more effectively if I proceed at once to the sources whence the profits of life assurance are derived. These comprise—

(1.) A lighter mortality-experience than that anticipated and provided-for in the premiums and valuations. This source is of comparatively insignificant dimensions, for if a measure of mortality has been selected in consistency with the experience which has actually occurred, the beneficial fluctuations of one period will, on natural and intelligible grounds, be succeeded by adverse oscillations at a subsequent stage, and *vice-versâ*. And the meaningless statement recited in the annual reports of many companies that the actual deaths have proved inferior to the number expected is a mere delusion as regards surplus from mortality, which should long ago have disappeared from the records of any office where precision of language is the reflection of reality of fact. The case in which a permanent profit would be realised from mortality would occur where the premiums were based upon a rate of death known to be intrinsically superior to that likely to prevail among the specialised class of members admitted into the society. This exception occasionally presented itself in former days in what were then termed "class" offices—offices, that is to say, which appealed with virtual exclusiveness to a particular section of lives, clergymen, *e.g.*,—but it no longer exists since, in compliance with the necessities of competition, these isolated societies have expanded their range of membership, though still endeavouring to retain, in this wider scope, the standard of acceptance which originally constituted their characteristic and determinate rule. In the experience of a prominent company—the sole evidence of the kind which has been published, though it is undoubtedly confirmed by the records of other offices—the surplus from mortality, determined upon a recognised mode of assessment, amounted, during a period of 20 years, to about 12 per cent. only of the entire profit realised.

(2.) A genuine profit arises from economy of management, and is dependent upon precisely the same conditions as those which prove effective in any department of commercial industry—the trained sagacity and skill of the administrator, and the rare capacity, in imitation of the universal formula in nature, of employing the simplest means for the accomplishment of the widest ends. The source for expenditure chiefly lies in the addition to the premium for the risk of death which I have explained, and its wise utilization reveals, or fails to reveal, the power of management of the actuary. The most ill-equipped administrator can obtain whatever amount of business he desires by sufficiently lavish disbursement, but one of the critical differences between actuary and actuary consists, not merely of native and developed ability of control, but essentially of that steadfast intellectual foresight and moral tenacity which render every article of expenditure deliberately subservient to the creation of financial benefit to the persons whose interests he holds in inviolable trust—benefit first, in the formation of impregnable reserves, and, next, in the periodical distribution of increasing realised profits. The expenses of a company are predominantly attributable to the acquisition of new business. I have ascertained, from an examination of the Board of Trade returns, that, even limiting the survey to offices which transact a steady and moderate, though adequate, business, the commission and expenses in respect of each year's acquisition is 83 per cent. of the premiums received upon that accession. And, as an aid in the discriminative criticism of the expense-ratios of companies, I have further ascertained, by the analysis of the several

companies' accounts, that the cost, as we should expect, is a function of the average amount of the new policies secured; so that where the assurances obtained consist mainly of policies of upwards of £900, the expense is nearly 22 per cent. less than that connected with new policies which, on the average, do not exceed £300 each. Regarding then the initial cost of new business, which I have thus deduced from the official returns—the normal charge, we might almost term it—for companies which do not inordinately and improvidently covet extravagant figures, what must be the wasteful encroachment upon the new premium income where the most prodigal efforts are squandered to attract needlessly-augmented numbers of fresh members! For excessive additions to the constituency of a company furnish in no sense an index of correspondingly remunerative acquisitions to the policy-holders. We all tend to a failing in favour of mere magnitude; forgetful frequently of the unquestionable truth that vast volumes of business are not necessarily an indication of equivalently increased profits—very generally, the reverse. For complete misapprehension and delusion are at once produced if we measure the extent of fresh accessions in insurance by considerations which appertain to ordinary commercial trade. In trading, it is often asserted, and justly so, that the profit upon each article, in some branches is so infinitesimal, that were it not for an enormous multiplicity of transactions the business would need to be abandoned. The vital difference between the two cases is this—that every new policy acquired requires a cash reserve to be immediately formed as a provision for its ultimate payment. And my practical conclusion is that the present mania for extravagant figures, as the subject of (really baseless) laudation in the annual reports, will surely find its Nemesis—as, in some instances, retribution has already arrived—in a diminution of surplus, and a consequent restriction of the genuine interests of the policy-holders, whose position and prospects should be the supremest care. If the members secured each year be sufficient to ensure the integrity of average results in experience,—and this adequacy is imperative for the maintenance of a continuing corporation,—all excursions beyond that protective and remunerative limit,—fluctuating in its range, I admit,—are not ultimately beneficial. This judgment affords no ground for supineness in energy of enterprise or alacrity of resource: it simply embodies the obvious doctrine,—whose failure of observance in any department of commercial activity signifies ill-success,—that expenditure in the minutest as in the widest mode should be governed not by the desire for excessive magnitude, but by the effort to produce the amplest profit and financial strength, and thus adequately to redeem the recognised trust for others which an assurance company implicitly accepts. The motive, or, more justly described, the imperative duty of an actuary should, by vigilant supervision over every element of administration, aim at leaving his company in a stabler and more prosperous condition on his retirement, or death, than that which he found existing when he assumed command.

(3.) The third, and most productive source of profit is the realisation of a clear rate of interest in excess of the rate on which the premiums and valuations are based. And in the company, whose experience I have already cited, it was ascertained that the percentage of the profit from this margin of interest amounted to 54 per cent. of the aggregate surplus during a period of 20 years. If, as is customarily the case, the rate of interest involved in the valuation be 3 per cent., and if a net uniform rate of $3\frac{3}{4}$ per cent. be obtained upon the invested and uninvested funds, the balance of $\frac{3}{4}$ per cent. per annum represents, at compound interest, the most important contribution to surplus, realised as it is upon the accumulated assets and the annual income. Thus, if we assume an average fund of £4,000,000, and a revenue of £400,000, a minimum yearly profit of £33,000 results from the surplus per-centage alone to which I have just alluded. A word may be interposed upon the unjust incidence of the present mode of assessment of the income-tax upon life assurance companies. This tax is levied at the source upon the entire interest received: interest being an essential factor in the payment of the sums assured, so far, then, as the tax is exacted (as it inequitably is) upon that portion of the interest which is equivalent to the valuation rate, so far is the tax deducted from principal and not from income. The significance of this element of interest suggests a brief reference to the equipment of the actuary and the duty of directors. In former years the actuary was essentially a mathematician: investments were generally restricted to British Government securities as a symbol of respectability, and to mortgages on land; and the stockbroker rendered the actuary

needless in the former department. In modern years any enlarged knowledge of mathematics —though, in my judgment, no actuary possesses that dominant scope and concentration of mind who is not a cultivator of the higher branches of this science—is not imperative beyond a sound and comprehensive grasp of mathematics generally; and the actuary discovers his specialised function in the capacity of commercial administration and signally in practised and sagacious mastery of finance.

The actuary in those anterior times was to a large extent a student, constructing the mathematical science of assurance and solving the problems in life contingencies which its expansion evolved; now he misses completely his destined vocation unless he is practically familiar with commercial transactions and causes, and equipped with that tact and happy judgment in business which are only possible through personal and observant contact with events and men. For, unfortunately, exceptional mathematical aptitude and acumen in affairs not infrequently exist in inverse ratio. The difficulty annually increases in securing appropriate and remunerative investments, and yet upon this pivot turns the future bonus - power of all the companies. This difficulty is occasioned by three or more causes —(1) the competition of the accumulated and augmenting funds of the various offices themselves, (2) the incursion of the general investing public into classes of securities which formerly were virtually restricted to corporations and to bodies possessed of vast resources, and (3) the gradual narrowing of the natural sources of materials and profitable cultivation as civilisation has advanced and the unexplored regions of the earth have successively been developed by capital and skill. But difficulties of investment should simply inspire directors and actuaries with keener powers of survey and wider though cautious enterprise. Experience has demonstrated that British Government securities — the finest the world has ever known — are totally unsuited to life offices, on account of the constantly fluctuating value of the principal and the inadequate return. International relations are now so intricate and complicated, and national intercourse so instant, that a mere breath of rumour in a previously unknown or neglected portion of the world is frequently sufficient to propagate a financial storm at home, and national funds, as the index of national sensitiveness, now respond with instantaneous vibrations. It is not within my province to express any preference for particular forms of investment, or to indicate what I conceive to be the appropriate modes of utilisation for the accumulations of companies. I confine myself to two observations: (1) The necessity of preserving a reasonable proportion between the different classes of investments which a company selects, so that if depression occur in one section of security, and thus deplete the fund, a simultaneous increase of value may be attached to others, and thus afford a counterpoise. During the recent severe depreciation in the values of stocks quoted on the Exchange, some companies felt compelled to write-off considerable amounts, or to divert from surplus a specific fund for possible losses; and this unhappy course would, to a large extent, have been rendered needless had the wise criterion of financial administration which I have expressed been thoughtfully observed, and a sagacious distribution of the assets been arranged in varied forms of investment not so liable to violent oscillations of value as those which are constantly and immediately marketable on the Exchange. (2) My second observation applies to the judicious widening of the customary scope of securities. The debentures of selected and stable industrial companies are worthy of attention; advances upon personal security (in conjunction with life policies) are remunerative when conducted on a definite plan under obvious conditions, and well deserving the constant care and supervision which they entail; while mortgages and investments abroad and in the colonies afford in many instances a sound and profitable range of securities where preliminary enquiry is devoted to taxation, the registration of titles, and the ownership of properties (in the event of foreclosure) by alien mortgagees. For we must remember that the directors of assurance companies are not restricted by the narrow boundaries and circumscribed authority of ordinary trustees. Their powers of investment are practically unconfined, and so should be their prevision and financial energy. Indeed, the mere existence of participating policy - holders furnishes demonstration that an integral portion of the duties of directors is to extend their excursions beyond the customary and monotonous limits of investment for the purpose of providing the amplest bonuses consistent with the discretionary caution which a wise and prudent man of business would exercise in his private affairs. Let me explode

also another empty and pretentious bubble whose flimsiness of texture is often mistaken for solidity of mass. The dictum of high interest signifying inferior security is one of those thoughtless aphorisms which mutilate the integrity of truth for the purpose of presenting a compact and impressive formula. It is a platitude which deceives men by its vagueness; a simulated truth whose reality is largely false. Postulating knowledge and circumspect sagacity, no danger exists in an unusual return of interest. The margin above the current rate will be frequently explained by the principle of supply and demand, or by the fitting supremacy of financial ability over duller and more commonplace wits, and a portion of the excess beyond the average return may be utilised as a sinking fund in redemption of part of the principal during the currency of the investment.

It may here be remarked, though the observation is one of mere speculative curiosity, that life assurance on the basis of the probabilities of life alone would still be practicable were money to cease earning interest. A simple calculation shows that if this contingency occurred our present scales of premium would only require to be increased by 1 per cent. upon the sum assured at every age to secure the payment of the claims precisely and punctually as they are provided at present. Profit, of course, would be absent, as its main origin would then have disappeared; the policy-holders would need to be charged independently for the expenses of management; while the reserves requisite as a guarantee for the fulfilment of the obligations would require to be most substantially enhanced.

In a direct manner I have adverted but slightly to other descriptions of insurance—Fire, Marine, and Accident.. The doctrine of probabilities certainly applies to the calculation of their premiums, though it may be predicted that the scientific processes which regulate the business of life assurance are not fully competent of adoption. For example, in those regions of insurance, we are confronted with the perplexity of partial and total losses, while every claim in life assurance must appertain to the latter category; and again, in fire insurance, in the classification of risks, and the consequent computation of premiums, the elements enter of the local supply of water, the facilities of means of extinction, and the contiguity of hazardous premises. The latter factor, it will be observed, corresponds to those cases in life assurance, where an applicant is, as it it termed, "rated-up" for inferior health or dangerous occupation, which remove him from the class of average lives. And in marine insurance, we perceive also the elements of salvage, particular and general average, the course of trade, with the seasonal and local influences of sky and sea, the record of the captain and the character of the builder of the vessel. The latter reference suggests the remark that, in every form of insurance—including life, the constituent of moral hazard is indiscriminately involved. We note also that fire and marine contracts are of a temporary nature, and include the power, on each side, of refusal to renew; thus doubly distinguishing them from life assurance engagements where this option resides only with the assured. Another distinctive feature is the fact that interest does not enter as an integral factor into the calculation of the rates and the reserve for unexpired risks. Still, there remains with all obvious differences, the fundamental fact, with other similarities, that premiums in these descriptions of insurance ultimately rest upon the ratio between receipts and claims, in other words, upon the determination of the probabilities of risk. If, for example, in fire insurance the current rate of commission and expenses be 35 per cent. of the premiums, and the required profit, 10 per cent., the year's losses in any particular category of risk should obviously fail to exceed 55 per cent; if then, on the examination of the combined statistics of several companies, it is ascertained that the rate of loss has proved to be 10 per cent. in excess of the expected 55 per cent. provisionally charged, it is clear that, upon the basis of this actual experience, the rates must be increased by 10 per cent. in order to equate the total charge upon the company with the relevant receipts. A closer approach to the scientific procedure of life assurance would consist in the comparison of the sums insured at risk, and the amounts which had become claims, but the introduction of this form of proportion would practically be difficult. I have referred to the addition to the premiums for profit, and on this subject I may mention that the chairman of one of our principal fire companies recently stated that, surveying the period of 10 years, from 1893 to 1903, the aggregate fire offices had realised an average annual return of 6¼ per cent. upon the combined consideration which they had received for the enormous risks which the

united capitals had sustained. This result finally disposes of the popular delusion that fire insurance is almost a fabled province of wealth. My next practical remark is that the recent disaster at San Francisco points to two important conditions of management: (1) the accumulation of fire funds in a higher proportion with a view to the prevention of sudden and extensive declensions in the market-values of the shares, and the maintenance of an equalisation of dividends (or, this suggestion may be embodied in the form of a specific conflagration fund which was urged and adopted by a former far-seeing fire underwriter); and (2) the judicious and inviolable observance, against the solicitations of competition, of a wise distribution of the proportionate amounts of risks both as regards nature and locality, in order to avoid an undue concentration of liability in any direction.

The developments of life assurance are generally in only a slight degree guided by the will, or preferences, or originality of the actuaries, but depend upon the changes of popular fashion and predilection, frequently unaccountable and obscure in their origin. I will direct your attention to a selection of some of the modes in which the popular fancy in modern times has found expression.

The major portion of practically every company's new business now consists of endowment assurances. I imagine that the discussion of old-age pensions has contributed to this extreme diversion of choice in the direction of this form of policy, since, in this mode, a pension in advanced age is obtained by the investment of the sum assured in securities, and a pension, also, in the negative shape of the relief from premiums. I do not conceive it to be a satisfactory substitute for the ancient practice of ordinary assurances payable at death. There exists, on the part of the policy-holders, the chance of the amount becoming subject to diminution in consequence of injudiciously selected securities, and the family provision being accordingly defeated, and, on the part of the companies—to the detriment again of the policy-holders—the difficulty and enhanced cost of obtaining business, particularly under the augmented stress of competition which will undoubtedly result, in order to replenish these serious successive abstractions of constituents. The old practice of the payment at death could be accompanied by the cessation in subsequent life of the burden of premiums by effecting the policy with the abrogation of premiums after the age of 60 or 65. I might notice here, in connection with endowment assurances, the provision commonly allowed, that, instead of accepting the sum assured on maturity, the policy-holder should receive an annuity equivalent to 5 per cent. (for example) upon the amount, with the ultimate receipt of the principal at death. I have no objection to urge to any of these modifications or schemes if they satisfy the public, but, of course, it should be clearly understood that so high a rate of interest as 5 per cent. cannot be manufactured by magic, and that, for example, if the valuation rate be 3 per cent., the additional 2 per cent. is contributed by the policy-holder himself in the form of an addition included in his premium.

Assessment companies, as they are termed, have, in modern times, disastrously occupied public attention. As this subject has assumed a prominent importance in America and some currency in this country, a few words of explanation will not be superfluous. In the early years of life the chance of dying in a year is comparatively small, but it increases annually with the advance of age. For example, at age 20 the probability of death occurring in one year is about 4 in 1,000, while at age 60 the corresponding chance is about 29 in 1,000, or about seven times greater; so that, omitting the consideration of expenses, the burden upon the policy-holder at those respective ages for the premium for one year's assurance of £1,000 is £3 18s. 5d. and £28 0s. 7d. In ordinary life assurance, as I have pointed out, those successive annual values of the liability under the contract are added together and the sum divided by an equalising annuity-value so as to ensure a uniform premium throughout life. The policy-holder accordingly knows year by year the precise sum he is required to discharge, and is freed from the possibility of augmentation. This uniform premium is too high in relation to the reduced probability of death at the early ages; but at the older ages it is not sufficient to meet the increased yearly risk; this ulterior deficiency, however, is balanced and compensated by the excesses of premium in the prior years being accumulated at interest (under the name of "Reserves"), and preserved intact, so that the integrity of the necessary provision is maintained without any advance in the rate of contribution. In the assessment system—to consider only its essential principle without the subsidiary details—the assured is required to provide each year the financial value of the risk for that year alone. Thus, in

the prior stages of life he pays considerably less than the policy-holder in an ordinary company, but as life proceeds and the chance of death increases the annual demands upon him continuously exceed the uniform premium. Let me submit an illustration with the exclusion, for clearness, of the element of cost. A person aged 30 assures for £1,000 on the ordinary plan, and his uniform premium for life is £17 18s. On the assessment scheme he would pay at age 30 for the ensuing year the premium of £5 15s. 6d., or 68 per cent. less than that required in the customary mode. But when he reaches the age of 60 the premium for the succeeding year is necessarily augmented to £28 0s. 7d., or 57 per cent. in excess of the uniform charge of £17 18s.; while on the attainment of age 70 the premium exacted for the next year's assurance would be £60 5s. 10d., or nearly 237 per cent. beyond the invariable rate. In the uniform system, as I have remarked, the excesses in the anterior years of the constant contribution beyond the rate applicable to particular years are retained in hand with their accumulation at interest, and thus supplement completely and exactly the annual deficiencies at the advanced ages, in the form of what is technically termed the Reserve. What is the obvious result of the assessment scheme? In the early years the policy-holder exults in his diminished burden, but as these annual payments necessarily increase with the augmented incidence of claims, the vigorous lives tend to desert the office in order to escape this successively intensified charge; sound and youthful lives are restrained from entering to restore the balance and reduce the average age; the weaker lives remain by reason of the difficulty or impossibility of assurance elsewhere in consequence of their deteriorated eligibility for acceptance; and the ruin of the company, with the defeated hopes of its members, are the inevitable issue.

We have been presented, too, with a system which dispenses with a medical examination at entry. But in all commercial transactions, as in the transformations of the forces of nature, no benefit can be secured without an exchange of corresponding value; and this plan is necessarily and justly attended by the condition that if death occur during the first year, the sum assured is reduced by two-thirds, or the amount payable is only £33 6s. 8d. per £100 assured; if the claim happen in the course of the second year a deduction is exacted of one-third, or £66 13s. 4d. is paid per £100 assured; while it is only if death be deferred to the third, or any subsequent year that the complete amount of the contract is discharged. Regarding the subject generally, policies of this nature do not satisfy the intentions of the assured. The most imperative necessity for a family-fund naturally exists in the early years of the assured's life when, if he died—having possessed insufficient time to accumulate any extraneous fund—the provision for the family, after the prescribed deduction, would be most seriously depleted. And yet the abatement is perfectly fair, for the chances of an undetected and speedily fatal disease—such as an aneurism or latent organic defect of the heart—must, in justice to the remaining policy-holders, be counteracted by adequate compensation.

The specialisation of risks is sometimes attempted, and notably in the formation of a scale of diminished premiums for teetotalers, accompanied by the exclusive division among themselves of the profits which their class produces. In the first place, no statistics have ever proved that teetotalism in comparison with moderate drinking is in itself the sole factor in the prolonged longevity which teetotalers as a body enjoy; a deduction of this character involves the fallacy of attributing to one selected cause a result which is really the product of several causes in combination. Teetotalers as a class do exhibit a longer existence than the average, but this consequence is due to the union of self-regarding qualities, thrift, industry, prudential care, which usually distinguish this body, and of which general character teetotalism is merely an indication and embodiment in *one* particular direction and form. There can be no objection but an advantage in teetotalers, if they please, combining themselves in one society of assurance, but there are difficulties of equity, I would point out, in those customary cases where in the same company teetotalers constitute one section of the assured, while moderate drinkers are relegated to a separate division. The assurance fund in these instances is an undivided, indivisible unity, formed indiscriminately by the contributions of both sections. Assume, then, that the teetotalers exclusively obtain the profit derived from their own premiums, in which segregated profits the ordinary section does not participate, are the teetotalers also in equity entitled to rely upon the aggregate common fund—which has been created equally by the

contributions of the moderate drinkers as their own—as a security for the payment of teetotal claims? If they separate themselves from the ordinary section in respect of one department of the common business—the production and distribution of profits—can they claim in justice that the entire fund, which is partly constructed by the moderate section's premiums, should form a general protection for their own particular claims at death? An assurance company, in my judgment, should be constituted a genuine commonwealth, all sharing proportionately the benefits and risks in a common trust, without disruption into sections, or attempted discrimination of privileged preferences.

I advert for a moment to Industrial assurance, which has attained so prominent a position in the general system. The social benefits of this appeal to the people are, from a national point of view, conspicuously manifest. The subjective habit of thrift cannot be arbitrarily manufactured; it must be evolved and developed by the stern teachings of life, the privations and punishments which attend improvidence; but in former years a distinct obstacle to the cultivation of financial prudence, consisted largely in the absence of assurance companies to whom the 1d. or 2d. per week of the provident poor could be committed. With the provision of sound channels for the investment of small premiums, which industrial companies now present, the practical realisation of habits of saving is possible. An objection which formerly existed has now happily been removed by the leading company. These smaller members previously received no portion of the profits which their weekly payments had substantially aided to create, and for a period this course was defensible, since industrial assurance was then passing through the experimental stage; but in quite recent times this unsatisfactory restriction—now that these offices have finally and successfully emerged from the trial, and with their enormous area of experience, stand completely secure — has beneficially been abolished, so that the fullest inducement is at present afforded for the advantageous cultivation of provident practices among the poor.

I have not dealt, from exigencies of time, with the question of the insolvency, winding-up, and extinction of companies; and, happily, the honourable history, on the whole, of life assurance enterprise in this country has removed this subject from practical discussion. In former days, starting with 1844, such a statement would have required a distinct qualification, but those disastrous times have merged into a more prosperous, conscientious, and worthy record. But I cannot refrain from expressing a judgment upon the subject of amalgamations and transfers of companies. In some unfortunate instances this course may conceivably be expedient or imperative for the protection or prosperity of the policy-holders—attributable, for example, to excessive and wasteful expenditure (for no life company has ever been seriously affected by abnormal mortality among its members), or occasioned by inefficiency of administration which, for some inherent reason, may be incompetent of reformation by the company itself. But many amalgamations and transfers are absolutely needless and injurious, and I am glad to observe public indications that the process is likely to receive a decisive check. They possess when they are unnecessary and indefensible—and most of them belong to this category—the following defects:—(1) they curtail the area of public choice in the selection for assurance; (2) they tend to create the bane of monopolies in a branch of commerce of supreme national import, with a consequent diminution of healthy competition in supplying most advantageously the varied public needs; and (3) the difficulty may occur that companies competent of success from their moderate size, and under a management which is able to devote effective attention to every element of organisation and enterprise, may not prove so prosperous when, by amalgamations and transfers, they attain a colossal magnitude which no single mind can adequately control and guide. Devolution of government, of course, is wise, but a limit is reached when devolution may prove inefficient in beneficial supervision.

To pass to a final remark upon the relation of assurance companies to the State, I would add that any attempt at supervision by Government beyond the boundaries prescribed by the Act of 1870 would, in my judgment, be disastrous. So long as companies are permitted to exercise unfettered their powers of responsible enterprise and administration; so long as the public are enabled, by the publication of returns to Government of essential information, to frame a sound estimate of the companies' position and technical provisions; all that is requisite in an enlightened and practical system of commerce and industry has been accomplished, and any transgression beyond these limits would not simply restrain individual and corporate origination and ex-

pansion to the permanent detriment of the public, but would undoubtedly also in principle entail upon the Government the gratuitous and utterly obnoxious financial responsibiliity for any misadventures, deficiencies, or catastrophes that might unhappily occur.

I conclude with a deserved eulogy upon the history of British Insurance which, in all departments of its enterprise and responsibilty, has earned our national pride for sagacity of adminstration and the honourable accomplishment of its trust.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said he did so as an ordinary member of the public and not as an expert or one in any way specially acquainted with insurance matters. He had been particularly struck with the fact that the author advocated that the commercial element should be diminished, and that the trust element should be increased. The insurance man if he did his duty was really in the position of a trustee. In all professions that element of trust should, at any rate, enter, and an organised profession usually had an etiquette and a code of its own. He might suggest in connection with the author's closing remarks, a difficulty which it seemed to him was always present, namely, that the ordinary insuring public could not estimate the relative value of the companies. Many men doubtless sought advice from those whom they thought knew, but practically a large proportion of the public was at the mercy of their own half information. Therefore it did seem to him to be of enormous importance that the training and organisation of the profession of insurance men should be on a par with that of the other professions. His only connection with insurance was that in his daily work he was brought into contact with colleagues who were specially engaged in giving teaching to insurance men. At the present time there was a proposal under consideration for the formation of an Insurance Institute for London, and in connection with it for further provision of insurance teaching. As a teacher he ventured to suggest that it was necessary to draw a distinction between what he might call the training of the private and the training of the general in any profession. There had been in this country a good deal of talk about technical education, but it had usually referred to the technical education of the privates of industry and commerce, not of the generals. He thought the problem of insurance training must be considered in two sections, first of all, the training of the privates, such as clerks and fire-insurance surveyors or the clerks of life-insurance companies. Such people obviously required the power of accurate statement. The general manager of one of the great accident insurance companies told him, a short time ago, that he required a large number of young men who possessed the power of expressing accurately just what they saw, and no more. He replied that he thought a demand was being made for one of the finest flowers of education, not always possessed by University graduates. In the next place, there was the education of the general, or what the author referred to as the administering actuary. In regard to life insurance here we had the Institute of Actuaries, but in regard to other departments of insurance much remained to be done. Various elements had to be taken into consideration in that regard. As he listened to the author it seemed to him there was practically no knowledge which would come amiss to a general in the profession of insurance; in other words, the very highest training obtainable was desirable, both general and professional. In giving that higher education a very special difficulty was involved. Too often the highly skilled mathematician lacked that knowledge of the world which was essential to the complete man of affairs. He ventured to suggest that sometimes they went the wrong way to work in the matter. It was not necessary that all the education should be given during the period of boyhood. It seemed to him that, during that period, a good general education might be given, after which a knowledge of the routine of the profession was required; and until it had been ascertained whether a young man had the aptitude for affairs, was it really worth while to seek to give him the higher training which was desired? What was required in this country, it seemed to him, was the man of affairs who possessed that very special knowledge, which so frequently seemed to incapacitate him as a man of affairs. Now this, he suggested, could be obtained in the way the army obtained it, *i.e.*, by the Staff College method. A period of army routine is interposed between school and college, so as to develope the practical sense. That practical sense was what the business man required, and what he missed so frequently in the University graduate. When that had been developed, the man should be sent, as in the Army, to the Staff College, if he showed those special powers which fitted him to be a general. At the present time insurance companies were asking their young men to equip themselves with that higher knowledge by evening work. The greatest credit was due to all young students who devoted time in the evening, after the day's work, to giving themselves increased knowledge; but he submitted to those who were responsible for the conduct of these great companies that a fair chance was not being given to the ablest young men, the leaders of the future, if they were compelled to obtain their knowledge in such manner. Not only were their brains tired by the day's work, but an hour was not long enough to lift them away from the narrow outlook of the office. Not only physical tiredness but

mental outlook was involved. It was impossible for a student to throw off the office the moment he arrived in a class-room and set to work on the the whole theory of his subject. Mr. Young's remark with regard to the rare quality of attaining by the simplest means the widest ends surely referred to the qualities of imagination and trained skill combined. If an artist, with a few strokes, produced a telling portrait, he did so by the joint use of high skill and imagination; and if a general, by a few movements, produced an entire change in the position of a war, he did it by his skill in discerning the position, and then his imagination gave him the idea which just fitted the situation and enabled him to attain the result. He suggested that there was a similar art of administration. As a rule it might be said that their administrators now arrived by accident. They were men who, by one chance or another, rose early, and blundered into the art of administration by experience. At the present time, affairs were becoming more complicated, and the competition of other countries had to be considered, and it seemed to him a thousand pities that all the experience available should go to waste, and have to be re-acquired by each man. He suggested there was a quicker way of making a man an administrator than starting him as the office boy, and that the key to administration, if the man once had the expert knowledge and the practical sense that came from business experience, lay in habitually nursing ideas, which ideas came from a broad outlook on to the world and on to the profession. The habit of entertaining those ideas came of a higher education. One branch of insurance, the life department, had been highly organised, but the other branches had not, and were now being considered by the calling generally. He submitted, not as one having experience of insurance companies, but as one who had some experience in education, especially education in connection with affairs, that a distinction must be made between the early stage through which all entrants to the calling ought to pass, and the later stage which he thought could only be imperfectly dealt with in evening classes. Those who had acquired the practical sense and were obviously destined for promotion, should have a little breathing space given to them away from routine for the purpose of looking at those great problems of ethics, mathematics, common politics, and of the world generally which had been exemplified in Mr. Young's paper.

Mr. A. H. BAILY thought sufficient emphasis had not been laid on the fact that the life department of insurance companies was already highly organised, and actuarial science placed on a scientific footing. The actuary of a life insurance company had to deal with many branches of finance, such as the granting of annuities, the investment of funds in proper securities, and all kinds of mathematical problems. He did not think the author had sufficiently discriminated between the life offices and the fire offices. For instance, in the one there was a contract of insurance, and in the other a contract of assurance. In fire companies the insurance policy was a contract of indemnity, but in life insurance the contract was an assurance of a specific sum to be paid at death generally. Two totally different contracts were involved, based on totally different principles.

Mr. F. R. SELLER said that, as essentially a fire man and not a life man, he had been particularly interested in the way in which the author compared the life and fire departments by dividing them up into their various branches or divisions, in the case of life with regard to the nature of the trade in which the particular man insured was working, and in the case of fire to the different hazards and risks. With regard to the question of education, to which the Chairman had drawn attention, the actuaries of life insurance companies had for many years past adopted courses of education, and had studied the cases they obtained in their ordinary every-day work; but in the fire companies those facilities had not till lately been obtainable. Fire officers had had to pick up their work in a very great measure at places away from the office. For instance, a fire insurance surveyor's work was quite different from the ordinary orthodox surveyor's. He ought to have the surveyor's knowledge of the methods of measuring buildings, the methods of heating, and the provisions of the Building Acts, but he could not obtain such information at the insurance company's office. The new Insurance Federation had provided such information in the last year or two in London, and he looked forward in the hope that that Federation would supply the needs of the fire-insurance officials in the way that the Institute of Actuaries supplied the life-assurance officials. Several classes were now being held which the officials of the companies could attend. The Chairman's suggestion that the offices should allow men time during official hours to go to lectures or classes would be very beneficial if it were possible to carry it out, but with the keen competition that at present existed he could not see how that plan could be adopted. He could not help feeling, however, that evening lectures were very useful indeed, not only to members of the fire department but to those of the life department as well.

Mr. A. D. BESANT said he had listened with great interest to the Chairman's suggestion with regard to the possibility of giving the coming leaders in insurance companies a sort of vacation, or holiday, from their official duties in order to perfect their knowledge. The keynote of the whole subject was that a young man in an office had to make his living, which was provided for him by the managers, who paid his salary. There was not in insurance companies, as at the Bar and in other professions, a sort of leisured class, who had a certain amount of time during which they could be students, and students alone. Nearly all the young men in insurance

companies had to enter an office to begin with. If they went to the University first, and entered an office at the age of 21 or 22 it was generalfy found that, to put it colloquially, they were too big for their boots; and it was found that the best men for the coming managers were those who had gone through the whole mill. In saying that he did not at all desire to disparage what the Chairman had stated, because if it were possible to pick out the man whom the manager looked on as his natural successor and give him the opportunity, an ideal state of affairs would be obtained, which, if it could be carried out, would be the most effective means of training a company could well devise for its future managers. From the point of view of a Manager, the work of an office depended so much on the members of the staff, as a whole, that one could no more take away his best assistant in times of stress than keep the place open for him for six months, when someone else, to a great extent, would have filled the position which he had occupied up to that point. He was especially glad to notice the importance which Mr. Young had attached to the question of expenses, which in the present day had attracted the widest possible attention. He did not think, however, it had always been considered on a fundamental basis. There were some expenses which were justifiable, and other expenses for mere expansion which were not. Those in the former category were expenses connected with supervision, the investigation of all sorts of questions connected with lives, by means of which bigger mortality profits might, he thought, be obtained than some offices had gained in the past. In other words, it was worth while to spend two or five guineas more in medical expenses if by so doing an early claim could be avoided. The company would gain in the long run, by spending a little more money, bigger mortality profits; and although nominally the expenses, simply considered as a percentage of the income, might be a little high, the surplus and bonus would be so much higher that they would make up for it. Another point of enormous importance to which the author had referred was the question of the size of an office as compared with supervision. He thought the author would agree with him when he stated that a moderate sized office was the best for all parties. In the first place, it was best for the supervision, because one man at the top could control the whole business in essentials although not of course in details; he could watch individual cases and investments, and put his finger on any weak spot in the organisation. In a big office he did not think that was possible, because although the greatest possible genius might be at the top he had to depend on other people who were less gifted. From that point of view he thought Mr. Young's remarks with regard to amalgamations were of the utmost importance. The mania of the moment seemed to be that the usefulness of a middle-sized office was a thing of the past, and that all the eggs should be placed in one basket, a few monster companies being formed which would control the whole market. He did not believe that, in the long run, it would be found that the policy was for the benefit of the offices, the shareholders, or the policy-holders.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Young for his instructive paper, thought it was extremely valuable to the public generally that the ripe experience of professional men like Mr. Young should be put in such a form as to be understood by the people. Those directly interested in insurance owed Mr. Young a debt of gratitude for coming forward and putting before the public the very high ideal he had set forth.

The resolution of thanks was put and carried unanimously.

Mr. YOUNG, in reply, desired to express his grateful acknowledgments to the audience for the manner in which they had listened to his remarks, which were the outcome of forty years of professional experience, and which, especially in relation to the disastrous manner in which insurance was now being conducted, in the way of reckless expenditure and equally reckless amalgamations, which involved expenditure to the serious detriment of the policy-holders, were inspired with the utmost earnestness and seriousness.

GOLD MINING IN AUSTRALASIA.

Since the first discovery in 1851 of gold in Australasia, nearly 140,000,000 ounces of gold have been produced in the various States, over one-half of which was furnished by Victoria. Prior to 1898 Victoria was almost invariably the leading gold-producing State of the group, but in 1904 its yield was about 60,400 ounces less than in Queensland and 1,522,000 ounces less than in Western Australia, which has in recent years increased its production by leaps and bounds from 110,000 ounces in 1893 to more than two and a third million ounces in 1904. In Western Australia, prior to 1898, the entire gold production amounted in value to approximately £5,000,000, but in that year work was begun in earnest with the result that in the succeeding twelve months over £4,000,000 was taken out. In 1901 the value of the production of the gold mines was £6,700,000, in 1902 £7,600,000, in 1903 £8,300,000, in 1904 £8,429,000, in 1905 £7,800,000. For several years the problem of a water supply for the goldfields was most difficult to solve, for about four hundred miles from Perth, the capital of the State of Western Australia, there are no rivers, few natural supplies of surface water, and the rainfall is light. The vital importance of overcoming this difficulty was recognised by the State, and some idea of the magnitude of the undertaking may be formed by the cost of the construction which amounted to over £3,000,000. In

1896 the Premier of the State obtained the approval of the Legislature to an expenditure of £2,500,000 for the provision of a supply of 5,000,000 gallons of water a day. The work was energetically pushed on, and brought to a successful completion in 1903. The supply, which is now regarded as adequate to the demands of the gold fields, is pumped 351 miles. Fully 18,000 men are engaged in mining, and the wages paid are sufficiently high to induce first-class miners to remain permanently employed. In the goldfields the value of mining machinery in use amounts approximately to £4,000,000, and there have been erected about 4,000 stamps. These figures show conclusively the splendid industry that has been built up, and all conditions now point to a continuance of the prosperous conditions.

Victoria, among the eastern States, still holds its prestige as the chief producer of gold in these States. The bulk of the yield in 1905 was, according to the "Mineral Industry in the United States and other Countries," contributed by the Bendigo field, and although the output was less by about 33,000 ounces than that of 1904—which was the highest for the previous thirty years—still it was such as to furnish unmistable evidence of the richness and permanence of the reefs. In the New Chum Railway and the Victoria quartz mines, the existence of reefs carrying gold at the depths of 4,230 feet and 4,090 feet respectively, was demonstrated during the year. The aggregate returns from the Ballarat district varied little from those of the preceding year. The yields from the mines at Walhalla and Beringa show that the industry has made headway in these centres. The total value of the gold produced in Victoria in 1905 amounted to £3,217,000, as compared with £3,296,000 in 1904. In Queensland, gold deposits have contributed more than any circumstance to the rapid advancement of that State, the value of the total output of this metal to the end of 1905, from the first record being, according to official returns, £1,955,000; and the estimated value of the machinery at present employed in connection with the gold and mineral fields of the State in working the mines and reducing the ore, £1,935,000. A geological survey of the State has enabled the auriferous districts to be mapped out. They cover a considerable area in Queensland amounting to about 32,000 square miles. The leading gold districts are Chartered Towers, Gympie, and Mount Morgan. The gold production of Queensland has been steadily progressive, while per head of the population engaged in winning gold Queensland produces more than double that of Victoria, and more than three times that of New South Wales and New Zealand. The value of the gold yield in 1904 was £2,715,000, and the production for 1905 is estimated at £2,550,000. In New South Wales there are twelve gold mining districts—Bathurst, Mudgee, Tambaroora and Turon, Lachlan, Tumut and Adelong, Southern Hunter and Macleay, Peel and Uralla, New England, Clarence and Richmond, Cobar and Albert. The amount of gold produced in the State to the end of 1905 is estimated at 12,532,651 ounces fine, valued at £53,235,000. The production of gold during 1905 was valued at £1,165,000, as compared with £1,146,109 in the preceding year—an increase of £18,904. The gold obtained by the dredges during the year 1905 amounted to 32,038 ounces fine, valued at £136,090 —an increase of £12,434 on that of the previous year. The gold yield for the first nine months of 1906 was valued at £832,066, compared with £804,043 for the same period of 1905, thus showing an increase of £28,023. As in preceding years, the Cobar field in 1905 contributed much the largest output of gold, the yield being 54,237 ounces. The Mount Boppy Gold Mine still further augmented its output during the year. The Wyalong Field ranks next in importance. Other divisions which contributed satisfactory yields were Araluen, Wellington, Forbes, Stuart Town, Adelong, Orange, Peak Hill, and Sofala. Although the gold yield of Tasmania is small as compared with the other Australian States, it shows good progress. The production in 1904 was 65,921 ounces, valued at £280,000, and in 1905 67,897 ounces, with a value of £290,000. In South Australia the yield of gold is lower than in Tasmania, the quantity produced in 1904 being 34,079 ounces only. The natural mineral resources of New Zealand are very great, and have exercised in the past a most important influence on the development and progress of the colony. Gold to the value of £67,231,000 was, according to the New Zealand Registrar-General, obtained prior to the 31st December, 1905, the value of the production in 1905 having been £2,094,000. In the earliest years the gold was obtained from alluvial diggings, but at the present time the greatest quantity is taken from gold-bearing quartz, which is distributed widely through several parts of the colony, and thus there is much better prospect of the permanency of this industry than alluvial diggings alone could give. Of the gold entered for exportation during the year ended March 31st, 1906—viz., 526,000 ounces, representing a value of £2,118,000—about 55 per cent. came out of quartz mines, but if the total yield of gold obtained in the colony be taken, the value of which to March 31st, 1906, is £67,754,000, about 25 per cent. came from quartz mines and 75 per cent. from alluvial workings. Gold dredging in New Zealand is now firmly established as an industry, and in Otago and Southland it maintains a high degree of efficiency and gold-producing results. In Otago 95 dredges were employed all the year round in 1905, and 50 in Southland. The Electric Company's No. 1 dredge's return of 1,273 ounces for five days' actual dredging in 1904 still remains the record of gold won for one week's dredging in New Zealand. On the West coast of the Middle Island the value of gold won was £103,277 by forty dredges. The total number of gold miners employed in 1905 was 9,362, as against 10,898 for the previous year. In some places, more

especially in Otago, Nelson, and on the West coast, many of the miners do not depend entirely on mining, but employ a part of their time in farming and other pursuits. The total value of the gold production of Australasia to the end of the year 1904 is stated to be £512,208,000.

THE COMMERCIAL IMPORTANCE OF ZANZIBAR.

The island of Zanzibar has been under British protection since 1890. It is the great storehouse and distributing centre for trade of the whole East African coast, although with the development of the resources of the mainland, and increased shipping facilities of the several mainland ports, its relative commercial importance is not so great as in former years. The islands of Zanzibar and Pemba (to the north) constitute the principal portions of the domain of the Sultan of Zanzibar. Zanzibar is the larger. It is of coral origin, about fifty miles in length and twenty miles in width, with low-lying hills and fertile valleys. These two islands produce about 90 per cent. of the clove crop of the entire world, in addition to large quantities of copra from the great number of cocoanut palms grown there. The native population, estimated at from 200,000 to 300,000, has made no material advance in the past half century towards taking up European customs, and are, as a mass, afflicted with the indolence found among native tribes generally. The white population does not exceed 500, mostly civil and military officials of the British Government and their families, the representatives of foreign Governments accredited to the Sultan of Zanzibar, and the representatives of those foreign houses having branches there, engaged in foreign trade. The natives are employed for the most part on the clove shambas or farms, the cocoanut groves, in preparing the copra for market, in fishing, loading and discharging ship's cargoes, and on public works. The local business is in the hands of Indian traders and shopkeepers. Household and domestic positions are filled by Goanese, and some few natives.

It is not as a producing centre that Zanzibar takes its commercial importance, but rather from its geographical relation to the Continent of Africa, to the Indian and Arabian coasts, and to the fine harbour on which is situated the town of Zanzibar. In a recent report by a special agent of the United States Government, on the importance of Zanzibar as a distributing point, it is stated that the islands of Zanzibar and Pemba form a natural breakwater between the African coast and the monsoons which sweep over the Indian Ocean, and the harbour has presented for centuries an ideal base for the exchange of foreign-made commodities for the slaves and native produce, brought in caravans from the interior of Africa to the ports on the mainland, and carried by Indian and Arabian dhows to Zanzibar, and thence to the ports of India and Arabia for distribution to their ultimate destinations. The channels thus formed by the movement of the commerce of the past centuries are difficult of change, and this will only be accomplished through the expenditure of much money and effort. The Uganda Railway of British East Africa has contributed greatly to the diversion to Mombasa of those products which formerly were brought by human carriers from the regions surrounding the great lakes of Central Africa, destined for Zanzibar. The harbour improvements at Kilindini, on Mombasa Island, will offer further inducements for transhipping goods at that point direct to the Uganda Railway, which at present is impossible of accomplishment. The ship subsidies given by the German Government, the development of German East Africa, the improvement of its chief port (Dar-es-Salaam), through the extension of harbour improvements and warehouse facilities, and the extension of the railway now under construction from that port to the interior, will induce a greater annual volume of trade at the last named port at the expense of Zanzibar.

As a distributing port, Zanzibar will, however, undoubtedly retain its supremacy in the East African trade over all others for many years to come, as there is much of the movement of the mainland produce confined necessarily to sailing dhows, which offer cheap transportation, and for the further reason that practically the entire trade with the natives of Africa is in the hands of Indian traders, who obtain their supplies of "trade goods" at Zanzibar from the old-established branches of the Bombay firms in exchange for the produce obtained from the native Africans. The basis of the business operations between themselves, and with the natives, is such as to make it difficult for Europeans or Americans to offer such competition as to make any serious inroad into their control. Consequently, those now striving for a share in this trade find it to their advantage to get into the commercial current, and go with it, rather than in oppositiou thereto. This is strongly evidenced by the practice of Germans of employing and supplying Indian traders with German made goods for the "barter trade" witb the natives in the interior of Africa. Realising its importance the leading houses have established at Zanzibar their principal, and often, only branches, relying on agencies to look after interests in other ports. Notwithstanding the commercial rivalry of other places, Zanzibar has maintained an annual average trade of over £2,000,000, about equally divided between the imports and exports of merchandise. The principal articles of import are building materials, coal, grain, groceries, glue, hides and skins, ivory, live stock, piece goods, rice and rubber. The chief articles of export are beads, cloves, copra, grain, groceries (chiefly in transit to local ports), gum copal, hides and skins, ivory, piece goods (chiefly in transit to mainland ports), rubber and sugar. The largest volume of the import trade is carried on with the United Kingdom, India and German East Africa, and of the export trade, with

these countries and France. In handling the very large transit trade, 212 ocean going steamships, aggregating 427,113 tons, entered the port of Zanzibar in 1905; of these, 59 were British vessels, 24 Austrian, 27 French, 95 German, and 7 of other nations. In addition to these, large numbers of sailing vessels, or dhows, carried various products of the mainland, of India, Arabia, and the islands of the Indian Ocean.

MANGANESE IN INDIA.

A good deal of attention is being bestowed in India on the production of manganese, the development of which betokens a new and flourishing industry. Nine or ten years ago it was not known that there were any deposits worth working. In 1896, however, important discoveries of manganese ore were made in the Vizianagram district of Madras, and a company was formed to work the deposits. Further investigations revealed the existence of the ore in the Central Provinces on the Mahableshwar plateau. Enquiry proved that there was in most countries an unlimited demand for it, and that the Indian product was of high commercial value. With regard to its uses, it is probable that 90 per cent. of the world's output of the ore is utilised in the manufacture of steel and iron. The steel so made is extraordinarily hard and tough, very difficult to work, and on this account is extensively used for many purposes where hardness, toughness, and great power to resist grinding wear are required. For mining drills and mining machinery of all kinds, it is in great demand. It is also required for axes and razors; manganese bronze, silver bronze, and ferro-silicon are other principal uses. One of the Indian journals draws attention to its bye-products, used in the manufacture of chlorine, bromine, bleaching powder, glass decolouriser, Leclanché's cell, preparation of oxygen on a small scale, disinfectants, and a variety of bye-products for colouring, dyeing, and other technical uses.

With regard to its export, manganese ore represents, according to the last Indian Trade Review, 82 per cent. of the value of all exported metals and manufactures thereof, other than hardware, the balance consisting of manufactures of brass, copper and iron. The trade received an enormous impulse from the failure of the Russian supplies (owing to internal disturbances) at Donetz and in the Caucasus. The exports from India thus rose from 180,945 tons in 1904-05, to 316,946 tons in 1905-06, making an increase of 75 per cent, while the value rose by 79 per cent. Mr. Noel-Paton states, that the rise in average value was a good deal greater than these figures would indicate, and that as the price of manganese in Europe has risen by about 50 per cent. there can be no doubt that large profits are at present being made.

In a recent lecture on the subject, Mr. Leigh Fermor, of the Indian Geological Department, draws attention to the following figures of production or exports:—

	Tons.
Russia, 1905	388,231
United States, 1904	383,246
India, 1905	282,334
Brazil, 1905	262,416
Greece, 1904	239,635

The figures of the last named, however, fell in 1905 to 4,645, showing that the mines had either given out or the Indian competition had driven the Greek mineral from the consuming markets. He is of opinion that when certain large deposits of manganese are discovered in Mysore, in the Dharwar and Sahara districts of Bombay, along the east coast and in parts of Chotia Nagpur, are worked, India will stand first as the largest producer of manganese in the world. Chemically the ore is allied to iron, cobalt and nickel, and in its pure metallic state is of grayish-white colour. It is very tough and is capable of cutting both glass and hardened steel, but it does not occur in nature in this pure state, but in combination with some 100 or so of metals. Mr. Fermor laid special stress in his lecture on the great advantages that would accrue from smelting the ore in India instead of increasing the expense by exporting the ore abroad and manufacturing it at a great distance from its place of origin. This the Tata Steel Works about to be established at Sini will do for the ore won in the Central Provinces, and similar works are expected to follow in other parts of India.

TRADE WITH BHUTAN.

The friendly part taken by the Tongsa Penlop, or chief Bhutanese ruler, in our recent negotiations with Tibet has had the effect of drawing attention to the commercial possibilities of Bhutan. Mr. J. C. White, the Political Agent in Sikkim, has several instructive comments to make on this in a recent report. He tells us that rice is the chief product, and that this is exported in large quantities into Tibet and finds its way to Lhasa. Wheat, barley, and buckwheat are grown in the upper valleys. In the eastern part stick lac is largely cultivated, but there is room for much improvement in regard to both quantity and methods. Systematic cultivation would pay, for the lac is in great demand and fetches good prices. In the lower valleys and hills there is an opening for rubber planting, for the *ficus elastica* grows naturally in all the valleys of Bhutan. There minerals are found, such as iron and copper, but it is not yet known whether these exist in paying quantities. There are factories turning out silk and cotton fabrics, especially the former. These factories belong to the chief officials. Bhutanese metal work is good, as may be seen from the gold, silver, and brass filagree on scabbards, teapots, pan boxes, &c. Their swords are made of good steel, highly tempered. The trade of Bhutan with Bengal is at present insignificant, but, as indicated above, there is plenty of room for its expansion.

HOME INDUSTRIES.

The Brewing Industry.—It will be interesting to watch the course of the brewing industry in the current year. It should go some way towards supplying the necessary data to form an opinion as to whether the diminution in the consumption of beer and spirits in the country in recent years is due in large or small measure, or in any measure at all, to the increasing temperance of the people. Since 1899 there has been an actual falling off in the clearances of beer for home consumption of 3½ million barrels, and this notwithstanding the growth in population of about 1 per cent. per annum. The decline in the consumption of beer since 1899 has equalled 10 per cent., and of spirits over 14 per cent. Referring to this remarkable shrinkage in his Budget speech of 1905 the then Chancellor of the Exchequer attributed it to "a wave of sobriety" flowing over the country, and his successor seems to be in agreement with him. If that be the true explanation then the present general and growing prosperity of the United Kingdom will not arrest the decline in the consumption of beer and spirits, but this explanation is contested by authorities equally entitled to respect, and who support the theory that the decline has been temporary and due to necessity. If that theory be the correct one then the present year will see not only a check in the decrease of consumption, which in fact, and as regards beer, has already commenced, but a certain measure of recovery. If this happens there will be considerable justification for the view that increased taxation, consequent upon a wasteful war, by diminishing the spending power of the people, and prejudicially affecting trade, explains the lessened demand for alcoholic liquors, and that the wave of sobriety has little or nothing to do with it. Undoubtedly the experience of the past has shown that in bad times the reduction of expenditure on luxuries is the first step in economy taken, and in this category may be placed the consumption of alcoholic liquors. Probably the truth will be found to be between the two extremes, and that whilst there will be recovery in the consumption of alcoholic liquors, assuming the year to be as prosperous as it promises to be, the recovery will not be quite commensurate with the growth of consumption in other directions, or the growth in the consumption of alcoholic liquors in earlier periods of industrial activity. Be that as it may there is ground for the opinion that the brewery industry has turned the corner. The licensing legislation of 1904 has compelled brewery companies to set aside from their profits certain sums to cover the compensation levied for license extinctions, and it is probable that this year or next further licensing legislation of a drastic character will be introduced, but notwithstanding these adverse points the opinion gains ground that the general prosperity will make 1907 a comparatively good year for the brewing industry.

Brewing Profits.—The popular idea that breweries make enormous profits, even after they have become joint stock companies, is not supported by the facts. In a recent number of the *Statist* it was shown that the net profits earned by 78 companies, with a total capital of £90,000,000, gave a return of 5·9 per cent. This cannot be deemed excessive, for the companies selected were among the soundest in the trade. The average rate on the debenture capital employed was about 4⅛ per cent., the average rate of dividend paid on the preference capital employed was about 4½ per cent., and the average dividend earned on the ordinary capital was a little over 10 per cent., but the average dividend distributed on the ordinary capital was 6¾ per cent. The £90,508,237 total capital was made up of debentures, £41,104,342; preference, £25,860,780; ordinary, £23,543,115. Of course, the average return was largely exceeded in some cases. For example, Nalder and Collyer's Brewery Company have returned 22½ per cent. on their ordinary stock (which, by the way, is only £130,000); Guinness, Son and Co., 22 per cent. (the amount of the ordinary stock being £2,500,000); Bass, Ratcliff, and Gretton, 14 per cent. (the amount of the ordinary stock being £1,360,000); and 26 of the 78 companies have paid 10 percent., or over, but the average was, as stated, 6¾ per cent. Examination will show that, at present prices, their debentures yield from 4½ per cent. to about 8 per cent. But with the probability of increased taxation in some form or another, and the capital difficulties incurred by many of the companies in reckless buying up of public houses, the ordinary shares of brewery companies cannot be considered as a good investment.

Commercial Intelligence.—The announcement of the President of the Board of Trade, made the other day to the Walsall Chamber of Commerce, that it is the intention of the Government to make certain changes in the Consular service, amongst other things to give British firms earlier information of trade doings abroad, has been received with general satisfaction by the mercantile community. "In future," said the President, "the Consuls will have to pass through the Intelligence Department of the Board of Trade, where we have information not merely from all the countries of the world, but where we come in close touch with the Chambers of Commerce, and where we get to know by inquiries what kind of information the traders want to know about, and what is passing abroad. Arrangements too, have been made, that in future all information which it is important for a particular trade of the country to see at once, shall be promptly telegraphed or sent to the Board of Trade, and they will send it along to the Chambers of Commerce." The last change is especially important. News to be of value to the merchant or trader must come to him promptly, and much of it that now comes through the Consular Department is belated. A comparison of German and more especially American methods

with our own shows how much more assistance the Consular service of our chief rivals gives to traders than our own. Under the new conditions, as sketched by the President of the Board of Trade, it may be hoped that this disparity will be lessened. It may be hoped, too, that the President will see his way to suggest to his colleagues the advisability of separating the duties of the commercial agent from those of the political consuls, the latter remaining under the control of the Foreign Office, the former being under the control of the Board of Trade. It must be seldom that the duties of the two offices, widely divergent as they are, can be efficiently performed by the one individual. But even when the proposals of the President of the Board of Trade are carried out, and if they do all that is expected of them, much will remain to be done in the way of obtaining better and fuller information from abroad. The trade of the United Kingdom with the Dominion and Australasia is of great and growing importance, and to some extent the Intelligence Department of the Board of Trade keeps traders acquainted with salient facts, but the information available remains fragmentary and inadequate. Take Canada. Our most formidable, indeed, our only formidable, rival for the trade of Canada is the United States, and American Consuls, and official commercial representatives of the United States in Canada are numerous and active. Canada, being a part of the British Empire, is without British Consuls, and British traders have to depend largely upon the excellent weekly and monthly reports issued by the Dominion Government. It is much the same with Australasia and South Africa. The lack of efficient organisation handicaps the British trader, and it may be hoped that now the Imperial Government is directing its attention to the whole matter, an effort will be made to improve the information supplied to traders as bearing upon colonial wants and opportunities.

Trade and Employment.—Without attempting to give the explanation, it is a remarkable fact that at the present time, when exports are increasing with a rapidity almost unprecedented in our commercial history, our total trade in 1906 having for the first time exceeded a thousand millions, there should be a marked increase in the number of the unemployed and pauperism. Taking the amount paid in wages, and comparing 1900 with 1906, the official figures relating to certain trades show the sum paid in 1906 was nearly four millions less than in 1900. If again the average number of unemployed among trades unionists is taken it will be found that the percentage has risen from 3·52 to 5·22, and it is reasonable to assume that the unemployment among unskilled workmen is larger than among unionists. Assuming, however, that it is no more than the 5·22 of trade unionists it means a large addition to the ranks of the unemployed. And naturally if unemployment has increased pauperism has also increased. In the return of pauperism just issued by the Local Government Board for the year ended Lady-day, 1906, a comparison is made between the years 1899 and last year, which shows that there has been an increase in the amount paid in out-door relief since 1899 of 33 per cent. in the case of London and 22 per cent. elsewhere. The official explanation is that it is due to depression of trade. Probably that is not the whole explanation, that some of the increase is due to less rigidity in the distribution of relief, and it may be that the returns for the year ending Lady-day, 1907, will be more favourable. But when all allowances are made, the figures as to unemployment and pauperism are not what might be expected, having regard to the growth of imports and exports, and suggest uneasy reflections as to our home trade.

The Coal Trade.—The price of coal continues to rise, and not because of any combine, but from legitimate causes. The exceptional demand for coal, from Germany, continues; the increased employment of steam shipping, and the decreased ability of Germany to supply her foreign coaling stations, have quickened the demand upon the British coalfields, whilst at home the industrial consumption has been larger. The result is seen in the rise in prices, which has been great. During the last three months, Cardiff steam coal has risen from 17s. to 20s.; Northumberland steam coal which, in November was 3s. higher than it had been a month or two earlier, now shows a further advance of 2s.; in Scotland the advance has been from 1s. to 2s. per ton above the prices current at the corresponding period of last year; in Lancashire "slack" has become very scarce. And not only is demand exceptionally active, advance in wages is being generally demanded. The Northumberland and Durham miners recently got an advance, but they are demanding another; in the Midlands the demands of the men have been conceded; in Scotland the advance of 3d. a day conceded in December has not prevented a further demand for a similar advance. And so elsewhere. Under these circumstances the public cannot be surprised at the higher prices they have to pay. Whether these prices will be maintained depends in large measure upon whether the export demand continues. Fortunately we are nearing the end of winter, when both household and gas-making consumption will decrease, but the German demand, upon which so much depends, shows no signs of abatement, but rather of increase.

OBITUARY.

LIONEL ROBERT ASHBURNER, C.S.I. — Mr. Ashburner, a member of the Committee of the Indian Section of the Society, died on the 26th January last, at his residence in Gloucester-place, W. He was born in 1827, and entered the Bombay service from

Haileybury College in 1848. He served in the revenue and judicial departments, in Gujerat. When the mutiny broke out he was appointed Police Superintendent of Kaira, with authority to raise a body of horse and foot militia to protect the eastern frontier of Gujerat from the waves of insurrection beating thereon from Central India. He was for a time Collector of Khandesh, a district on the northern edge of Deccan, among the population of which is the race of Bhils, respecting which Captain Barnes's paper was read before the Indian Section on January 24th (see p. 323). Subsequently he was advanced to the position of Commissioner of the Northern Division of Bombay Presidency. Five years later he became revenue member of the local Government under Sir Richard Temple. When Sir Richard returned to England in 1880 he acted as Governor for a period of six weeks pending the arrival of Sir James Fergusson. He retired in 1882, after 36 years of Indian service.

Professor Mendeléeff. — Dmitri Ivanovitch Mendeléeff, LL.D., For.Memb.R.S., the renowned Russian chemist, died on the 2nd inst. of inflammation of the lungs. He was born at Tobolsk, Siberia, on the 7th February, 1834, and received his early education at the Gymnasium of that place, of which his father was Director. In 1866 he became Professor of Chemistry in the University of St. Petersburgh, and shortly after the first edition of his great work, "Principles of Chemistry," was published, and in 1869 he brought his views on the Periodic Law before the Russian Chemical Society. In 1905 the third English translation of his "Principles" was published, which was translated from the seventh Russian edition. In this the author wrote, "In carefully preparing this edition I have not lost sight of the fact that I am hardly likely to publish another, and I have, therefore, in many cases spoken more definitely than formerly."

In 1882 Mendeléeff was awarded the Davy Medal of the Royal Society for his researches on the periodic classification of the elements, and in 1905 he received the Copley Medal, the greatest honour the Royal Society has to bestow. In 1896 he was elected an Honorary Corresponding Member of the Society of Arts.

GENERAL NOTES.

Exhibition of Printing.—It is announced that an International Exhibition of Printing and Fine Arts will be held in Paris from July to October next in the Grand Palais of the Champs Élysées under the authority of the Minister of Public Instruction. The offices of the British Section are at 2, 3 and 4, Cheapside, E.C., where all information about the exhibition can be obtained.

Uruguay.—Since Mr. Consul Kestell-Cornish reported on the harbour works of Monte Video last year considerable progress has been made with the port works. In his review of Uruguayan affairs just published (Cd. 2682), the Consul says that the prolongation of the eastern breakwater has been continued, and was expected to be completed by the end of the year (1906). The channel has been dredged up to a distance of 2,000 metres, giving an average depth of 25 feet. A portion of the centre port is being dredged to a depth of 26 feet, in order to allow of the entrance of the larger mail steamers. The construction of quay walls has been continued, and the greater number of the pillars required for Mole A are now completed. The work of reclaiming the land on the shores of Aguada has been continued, and the wooden mole will soon be open for river steamers. The channel is to be furnished with buoys provisionally until lighted buoys are provided, which are expected to be placed in position in the course of the present year.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday Evenings, at 8 o'clock:—

February 13.—"Motor Omnibuses." By Lord Montagu of Beaulieu. A. A. Campbell Swinton will preside.

February 20.—"Cold Storage and Food Supply." By Hal Williams. Sir Edward Montague Nelson, K.C.M.G., will preside.

February 27.—"Modern Typewriters and Accessories." By Arthur E. Morton, Examiner in Typewriting to the Society of Arts.

March 6.—"The Discovery of the South Eastern Coalfield." By Professor W. Boyd Dawkins, D.Sc., F.R.S. The Right Hon. Lord Harris, G.C.S.I., G.C.I.E., will preside.

March 13.—"Mediæval Stained Glass, its Production and Decay." By Noel Heaton, B.Sc.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 14.—"The Practical Side of Famine in India." By Sir Frederic S. P. Lely, K.C.I.E., C.S.I., late Chief Commissioner of the Central Provinces. The Right Hon. Lord Curzon of Kedleston, G.C.S.I., G.C.I.E., will preside.

March 14.—"The City of Madras." By Sir James Thomson, K.C.S.I., M.A., late Member of Council, Madras.

May 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By Sir Edward Charles Buck, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

May 30.—"Irrigation Colonies in India." By Laurence Robertson, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. This paper hus been unavoidably postponed from February 19th.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S., "Gold Mining and Gold Production." Three Lectures.

LECTURE III.—FEBRUARY 11.—*Gold Production.*—The crushing of the ore; the stamp mill—The extraction of gold by amalgamation; smelting; chlorination and cyanidation—Reforms in consequence of the tube mill and the filter press—Tube mill *versus* pan—Proposed abolition of the stamp battery—The depth of ores; surface and secondary enrichment—Mining costs and gold mining organization.

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.
February 25; March 4, 11.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. John Walter Gregory, "Gold Mining and Gold Production." (Lecture III.)

Mechanical Engineers, Storey's-gate, Westminster, 8 p.m. (Graduates' Lecture.) Dr. H. S. Hele-Shaw, "Aerial Navigation."

United Service Institution, Whitehall, S.W., 3 p.m. Col. Right Hon. Sir J. W. S. Macdonald, "The Organisation of Power Traction on Roads, for National Defence."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr Alfred A. Hudson, "The Ventilation of London."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Captain R. Amundsen, "To the North Magnetic Pole and through the North-West Passages."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. S. L. Hughes, "Parliament from the Press Gallery."

TUESDAY, FEB. 12...Asiatic, 22, Albemarle-street, W., 4 p.m. Professor E. G. Browne, "Account of Investigations into the History and Literature of the Hurúfí Sect, and its connection with the Bektáshí Order of Dervishes."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture I.)

University of London, South Kensington, S.W., 5 p.m. Baron D. Kikuchi, Inaugural Lecture on "Japanese Education."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Colonel R. E. B. Crompton's paper, "Modern Motor Vehicles."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Colonel Sir Donald Robertson, "Some Reflections on Modern India."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Annual Meeting.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, FEB. 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Lord Montagu of Beaulieu, "Motor Omnibuses."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. S. Tuke, "The Selection of Japanese Prints."

United Service Institution, Whitehall, S.W., 3 p.m. Vice-Admiral Sir Charles Campbell, "The Strategical Conditions of the North Sea as Improved by the Edinburgh and Glasgow Canal and Dover and Calais Tube Railway."

THURSDAY, FEB. 14...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir Frederick S. P. Lely, "The Practical Side of Famine in India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Junior Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Mr. Dion Clayton Calthrop, "The Pageant of History."

London Institution, Finsbury-circus, E.C., 3 p.m. Professor H. E. Armstrong, "Scientific Methods."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. Harker, "The Minute Structure of Signeous Rocks and their Significance."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, FEB. 15...Royal Institution, Albemarle-street, W., 9 p.m. Mr. J. F. Lister, "Foraminifera."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "The Place of Ugliness in Art."

Geological, Burlington-house, W. 3 p.m. Annual Meeting.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m. Annual Meeting.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Annual General Meeting. 2. Prof H. C. H. Carpenter and Mr. C. A. Edwards, Eighth Report to the Alloys Research Committee, "The Properties of the Alloys of Aluminium and Copper."

SATURDAY, FEB. 16...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture I.)

Journal of the Society of Arts.

No. 2,830. VOL. LV.

FRIDAY, FEBRUARY 15, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 20, 8 p.m. (Ordinary Meeting.) HAL WILLIAMS, "The Commercial Application of Refrigeration."

Further details of the Society's meetings will be found at the end of this number.

ALBERT MEDAL.

The Council of the Society of Arts attended at Marlborough House on Friday, the 8th inst., when his Royal Highness the Prince of Wales, President of the Society, presented the Albert Medal to Sir Joseph Wilson Swan, F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

The members of the Council present were:—Sir Steuart Colvin Bayley, K.C.S.I. (Chairman), the Duke of Abercorn, K.G., Sir James Blyth, Bart., Sir William Bousfield, LL.D. Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., Mr. W. C. Knight Clowes, Sir William Crookes, F.R.S., Mr. Robert Kaye Gray, Sir John Cameron Lamb, C.B., Sir Philip Magnus, M.P., the Hon. Richard Clere Parsons, Sir Westby Perceval, K.C.M.G., Sir William Preece, K.C.B., F.R.S., Sir Boverton Redwood, D.Sc., Sir Owen Roberts, D.C.L., Mr. Carmichael Thomas, Sir William Hood Treacher, K.C.M.G., Sir John Wolfe-Barry, K.C.B., F.R.S., with Sir Henry Trueman Wood, M.A. (Secretary), and Mr. Henry B. Wheatley (Assistant Secretary).

CANTOR LECTURES.

Professor JOHN WALTER GREGORY, D.Sc., F.R.S., delivered the third and last lecture of his course on "Gold Mining and Gold Production" on Monday evening, 11th inst., the particular subject being Gold Production. The lecturer described the crushing of the ore, the extraction of gold by amalgamation, smelting, chlorination and cyanidation, and then referred to changes in processes and machinery, ending with remarks on mining costs and gold mining organisation.

The CHAIRMAN proposed a vote of thanks to the lecturer, which was carried unanimously.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 14; THE RT. HON. LORD CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., in the chair.

The paper read was "The Practical Side of Famine in India," by SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I.

The paper and report of the discussion will be published in a future number of the *Journal*.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, January 29, 1907; T. G. JACKSON, R.A., in the chair.

The paper read was—

THE ARTISTIC TREATMENT OF THE EXTERIOR OF THE PIANOFORTE.

By WILLIAM DALE, F.S.A.

In dealing with the difficult subject of the art treatment of an object which by common consent is not artistic, I begin by craving your kind indulgence. It is my intention to deal with the subject very largely from an archæological standpoint. I am led to this by the very nature of my studies, which have lain among those keyboard instruments which preceded the pianoforte, and which in form were largely imitated by the early pianofortes. For this reason I am not at all sure that I am the best person you could have asked to read this paper. I am not in sympathy with a good deal of what is called decorative and artistic treatment to-day. I am also not in agreement with those who consider we cannot learn from or take lessons from the past, and that a machine-made thing may be as artistic as anything which is old, and which is admired only because it is old. May I be allowed to quote the opinion of one who, though perhaps not recognised generally as an authority on art, had a true perception of the beautiful and as sound a judgment on this question as any. I refer to the Rt. Hon. W. E. Gladstone.

Addressing an audience of working men at the Agricultural-hall, at a distribution of prizes gained at the National Workmen's Exhibition, Mr. Gladstone said in 1893:—

"There are many who believe that in the case of industrial productions it is a loss of time and pains to think about giving to them a character of beauty. It is this falsehood which we ought, if we can, to tear up by the roots. Let me reply to those who tell us so, that, on the contrary, the whole history of Greek art is a demonstration of the truth of that important and essential principle."

Later on in his address, passing to the subject of architecture, Mr. Gladstone continued:—

"There is this great peculiarity in the remains of early Christian architecture. In these remains beauty is not supplementary and occasional, but uniform and invariable. I am not now speaking of the works which were produced in the later Middle Ages, but of those works which present most of all the character of simplicity as their main characteristic. If you travel in Ireland on no account fail to examine the Glendalough churches. I do not suppose there is one of these churches which is 50 feet long. You might build any one of them for £500. But every line of one of these churches is instinct with beauty which the rudest and even untutored can hardly fail to recognise. There is a circumstance in architecture which terrifies me, and that is the tendency which appears to prevail in modern domestic architecture—I refer to its redundant ornamentation. There are a great number of new buildings in London—I hope I am not treading on any ones toes—with regard to which, if you look at them, you will find that the architect had either a horror or a dread of leaving bare a single square foot of wall. Why do we not wage a war against this excess of ornamentation? Excess of ornamentation is, of all things, the most hostile to a due appreciation of proportion, because it is in proportion to the perception of breadth and beauty and line, and in the adjustment of lines to one another, that the art lies, and in that you will find the hope of attaining high excellence in great works. I will mention to you the case of the exterior of Salisbury Cathedral. The man who wants to know what is beauty in stone—beauty not produced by ornamentation—should visit Salisbury, for there he will see less ornamentation on the exterior of the building than in any Cathedral, and, I believe, in a great many domestic houses in London. But if you want to see what can be done by simple beauty of outline, which is the foundation of all beauty, take a look at the exterior of Salisbury Cathedral. It is a model for all ages and all countries."

I would not have troubled you with this extract if I did not believe it had an important bearing on our subject, and I hope before I have done to be able to show you that the most successful attempt to render the pianoforte a work of art was made by one who was guided by similar principles to those laid down by Mr. Gladstone.

I have said that the modern piano is not an artistic object. The inexorable law of evolution is responsible for this. The square pianos of the eighteenth century were well proportioned, and admitted of some decorative treatment, which, though simple, was often most happy. But as the construction of the square piano improved, to meet the musical requirements of succeeding generations, its size and unwieldiness increased, until it was finally improved off the face of the earth. The grand pianos of the eighteenth century were built so nearly upon the lines of the old harpsichords that you could not tell the difference until you opened them. Early in

the nineteenth century their form began to deteriorate as their interior construction altered. The frame, or stand, with its familiar stretcher was abandoned for legs, and the pedals, instead of being attached to the front legs, were disposed of in a lyre-shaped construction depending from the body of the instrument. As iron bars and iron framing came in, and the tension of the strings largely increased, the case of the piano had to be made increasingly strong. Its elegant proportions vanished, and the legs soon became elephantine in size. A tendency has lately sprung up to revert to the smaller sized grands. But the exigencies of modern compass require the key-board to be wide, and the result is a horizontal instrument almost square. These pianofortes, although called by the endearing titles of "Mignon," "Bijou," and "Baby Grands," are ugly in inverse proportion to the sweetness of the names they bear.

The upright pianoforte is only a little more than a hundred years old. The early ones, which were tall, were known as cabinets and upright grands, often with an imposing cornice on the top, quite architectural in its character, and not unlike a Chippendale bookcase—though generally the appearance was spoiled by a wealth of silk curtain fluted and radiated from the centre.

The popular upright piano, known as the "Cottage," has always been as unpretentious as its humble name indicates. Quite one of the earliest, made by Isaac Hawkins in 1800, was, however, decorated with ormolu, and its folding keyboard made it neat and sightly. Modern attempts to treat the ordinary cottage piano æsthetically seem to result in producing an instrument more eccentric and bizarre than artistic. One, called for some occult reason the "Manxman," has doors, and opens like a kitchen cupboard; another, known as the "Medieval English," has for its leading idea the candlesticks, which shoot straight up from the ground in continuation of the legs.

It is necessary to remind those who design such instruments that to produce a case of such a form that no one would imagine it contained a pianoforte is not treating that instrument artistically.

I am fully aware of the difficulties which beset the path of the pianofore-maker who may be artistically inclined. The public will have iron-framed and powerful sounding instruments, and such require cases of a certain amount of massiveness. Herein largely lies the difficulty of treating them artistically. Yet it is germane to the subject to study carefully and reverently the forms and decoration of the instruments of a bygone age, and to see if it is at all possible to translate into modern practice the principles which guided the manufacturers of those times.

Of all the manufacturers of musical instruments none were more noted than the famous family of the Rückers, of which there were several generations working in Antwerp as harpsichord makers from the middle of the sixteenth century until the closing years of the seventeenth. I dare not linger to describe the sweet silvery tone of these wonderful instruments, several of which I have known and played. In the Rückers' family art and handicraft were allied. They were members of the Guild of St. Luke, the painters' guild, because their instruments were painted. The case was usually black, and not often decorated, but, on opening the top, all was changed. The interior of the lid was filled with some pleasing subject, painted by a master hand. The sounding-board, with its carved rose and trade-mark, was covered with a design of flowers, and the edges of the case appearing above the sound-board were enamelled a lovely red—the despair of modern imitators. When not painted, the lid was inscribed with mottoes. In a volume of the unpublished papers of Peter Paul Rubens, which appeared in 1859, is a letter dated 1638, which passed between the painter, Sir Balthazar Gerbier (then in Brussels) and Sir F. Windebank, private secretary to Charles I. It related to the purchase of a Rückers harpsichord for the King of England. The instrument is described as by Hans Rückers the younger, and painted with the subject of Cupid and Psyche, by Rubens. The price was to be £30, without the painting £15. It was eventually purchased and sent to England, but did not please the king on account of its short compass. On being appealed to, Hans Rückers refused to alter the compass. Many such harpsichords must have found their way to England. It was my privilege in 1879 to see one by Andreas Rückers completely restored. Some 100 years earlier it had been previously restored, and a fresh case of mahogany put to it, but the painting and decoration of the interior were unaltered. The painting of the inside of the top I was able to identify as the work of Van der Meulen. It was brought under the notice of Sir Edward (then Mr.) Burne-Jones, and it was largely

this instrument that inspired his conception of the famous "Orpheus" piano, which, later on, I shall describe.

With the mention of the Ruckers family I may dismiss foreign instruments. The early Italian spinets, it is true, were decorated in various ways, some in embossed leather and some with precious stones, and some with painting. Examples of such can be seen at South Kensington. As, however, these instruments were not placed upon stands, but laid upon the table, they had very little in common with pianofortes, and do not fall within the scope of my paper. The English spinet, first made in England about the middle of the seventeenth century, was derived from the Italian spinet. No decoration was employed upon the case, but the form was so beautiful and well-proportioned that I am bound to refer to it. Pepys, in his Diary, records, in his well-known style, repeated visits to Haward to purchase a spinet, and after it was brought home he next buys a stand for the same. This instrument reached its greatest perfection in the days of Queen Anne. Nothing has ever equalled the form of the spinets made by John and Thomas Hitchcock. The picture which you will presently see is of one which was the favourite instrument of the Princess Amelia, youngest daughter of George III. A kindred instrument to the spinet was the virginal; indeed, spinets were often called such, although it is usual amongst connoisseurs to restrict the term virginal to the oblong or coffer-shaped instrument. One of them, by Liversedge, undoubtedly English and seventeenth century, is the only instance I know of a painted English spinet or virginal. It is the property of Mr. Arthur Hill, F.S.A., and was once Dr. Rimbault's. The painting, somewhat rudely executed, it is said, represents ladies walking in the Mall. The harpsichords made in England, like the spinets, were not ornamented. This is somewhat singular, as both the great makers of the eighteenth century, Kirkman and Shudi, derived their art from the House of Rückers. Their cabinet-work was, however, excellent, and the marqueterie stringing, and veneering in panels was very beautiful. I possess a double harpsichord, made in 1770, when Shudi had just taken Broadwood into partnership, which is so finished, and has in addition long strap hinges of brass, which are a very simple and effective decoration.

The first square pianos made in England between 1760 and 1780, were of simple rectangular form, and placed upon a plain stand. Soon after the latter date they greatly improved in appearance, and for about ten years the homely square piano was worthy to rank as a decorative object. It was placed on what was called a "French frame," that is a stand with tapering legs of Louise Seize pattern. Satin and tulip wood, and that beautiful wood, now so little known, called hare wood, was used for decoration, and some little brass work, which was technically known as furniture, was sparingly added. The space above the keys was used for a name-board. The name itself was inscribed on an oval of satin wood, written or engrossed with a quill pen. To the inlays one maker, Longman and Brodripp, of Cheapside, the forerunner of the firm of Collard, added a charming wreath of sweet peas on either side, painted with considerable skill. The proportions of the instruments were good, and it is probably from their winsome appearance that these old instruments, when they occasionally turn up, are often called spinets. Equal praise may also be given to the early grands, which, up to the close of the eighteenth century, carried on the form of the harpsichord. In fact, being somewhat smaller than the harpsichord, their lines were better, and this was particularly noticeable in the curve of the bent side.

In the year 1880, Sir Edward (then Mr.) Burne-Jones conceived the idea of treating the piano artistically. Here I wish to say that one of his aims was the production of a beautiful curve for the bent side, and it is a recollection which I think I alone retain, that in a quiet room in Golden-square he drew on a large sheet of paper in freehand a curve which he wished to be that of the piano he was designing. On testing this curve subsequently, its proportions were found to be exactly those of the grand pianos made in the last decade of the eighteenth century, by the firm in whose house he was. In searching the old books of Broadwood I have found at this period frequent mention of pianos decorated with medallions, and I have met with one instrument of the kind which has survived. It was dated 1798, and was sold at Christie's only a few years back. The medallions were Wedgwood's, they were sparingly placed round the sides and in the space above the keyboard, and had a charming effect, while the cost of the piano in ordinary cases could not have been greatly enhanced. I say in ordinary cases, because in 1796 Broadwood

had the commission to decorate a piano in this style, which was so remarkable that it deserves more than a passing mention. In February of that year the Spanish Ambassador, staying at Grenier's Hotel, in Jermyn-street, gave the order for a grand pianoforte superbly ornamented in satinwood case, with inlaid work and Wedgwood's and Tassie's medallions, &c. He is called "Le comte de Mopox et de Jarnico," but the entry is headed, "Prince of the Peace," for the piano was for "Don Manuel de Godoy," the handsome guardsman, the favourite of Queen Maria Louisa, whom Charles IV. of Spain raised to the rank of Minister of Foreign Affairs. The year before he had earned the title Prince of the Peace by concluding the treaty of Basle with the French Republic. Two months after his English-made piano reached the shores of Spain, he signed the treaty of San Ildefonso and declared war with England, initiating that series of disasters for his country which culminated at Trafalgar. The piano was not, however, apparently for himself. Sheraton's own design for the instrument, of which more than one copy exists, states that it was presented by Godoy to the Queen of Spain, to whose favour the rapid rise in his fortunes could alone be attributed. The instrument took four months to make, and left England for Bilbao on the 22nd of June. It is described as "a grand pianoforte, 6 octaves C to C, in satinwood case, ornamented with different woods with water-gilt mouldings and Wedgwood's and Tassie's medallions. The Prince of the Peace's arms, chased and gilt in burnished gold. 213 guineas —£223 13s. The Prince's portrait in front, by Taylor, £10 10s." It must, of course, be borne in mind that the relative value of money was then very much higher.

For many years I was familiar with Sheraton's design for this piano, and acquainted with the description of it I have quoted. To-night I am able to show you a photograph of the actual instrument. A few years ago a Parisian dealer in antiquities wrote to a lady in England, whom he knew to be a collector of things rare and curious, that he had a piano covered with medallions made by Broadwood, and dated 1796. It was none other than Godoy's present to the Queen of Spain, and it is now in a London drawing-room. Probably looted from Spain in the Napoleonic wars, it remained unknown, but well cared for during a number of years, most likely in some French chateau, until thrown into the market and purchased by this Parisian dealer. Taking it altogether, it is in splendid preservation. The satinwood has mellowed with age, the keys are unworn, and the medallions perfect. As it stands it is a good illustration of the warfare between the designer who wants to be artistic and the manufacturer who must obey the requirements of a musical instrument. Sheraton designed separate and unconnected legs for the piano. It was at a time when such a thing was not known, but the piano-maker appears to have given in and abolished the frame and stretcher. The pedals, which should have been attached to each front leg of the frame, were made to depend from the body of the piano, and a third pedal, added in the middle, acted upon a pad, which pressed against the sounding-board, producing a sourdine effect. This arrangement spoils the general effect of the lower part, and formed no portion of Sheraton's design. "The Prince's portrait in front, by Taylor," one looks for in vain. Above the key-board, surrounded by beautiful decorated work, is the oval where the maker's name and date were always written. In this case the name is written on the rail covering the dampers, and the oval is covered with a device not well put on. Here I should say was once the "Prince's portrait in front," a miniature, by Alexander Taylor, the miniaturist, for which he received £10 10s.

Alexander Taylor was an occasional exhibitor at the Royal Academy for 20 years, and, curiously enough, the last time he exhibited was 1796. Such a high price being paid, the portrait was most likely taken from life, and if so, the redoubtable Godoy must have been in England in the spring of 1796.

Before passing on to mention any decorated pianos of modern times, I should like to show you upon the screen some of the old instruments to which I have referred, viz.:—A spinet by Charles Haward; a spinet by John Hitchcock; a painted harpsichord; an English harpsichord by Shudi and Broadwood of 1770; a square piano, 1782; a grand piano of 1793; a cottage piano by Hawkins, 1810; the "Prince of Peace" piano of 1796.

In passing from the art of a bygone age to that of modern times, I am met with the difficulty of knowing where to choose. There are no leading piano-makers that have not at some time or other produced what are called art pianofortes, and some are showing such to-day. I fear if I were to attempt to describe them I should certainly omit

some I ought to have mentioned. Moreover, there is another reason why I should leave them alone. In nearly all instances they are the outcome of the taste of some private individual whose means have been unlimited, and shew a wealth of decoration and treatment which, in my humble opinion, it would not be wise to follow even if means permitted. It will be more practical to ask ourselves if the pianoforte attainable by folk of ordinary means cannot be made far more beautiful and artistic than it is.

Before dealing with this, the final part of my subject, I must mention two pianofortes designed by two of the greatest artists of the present generation, and also refer to a pianoforte designed by our chairman in 1892 for Mr. Athelstan Riley, a lantern slide of which I am able to shew you. The wood of the case is mahogany, stained to a very dark green, almost black, affording an excellent ground work for the inlays of various woods, mother-of pearl and tortoise-shell up the top of the lid. The inside of the lid is decorated with Gesso gilt on a red ground — the nearest approach to the "Ruckers'" red I have seen. The black keys are inlaid with ivory, and the fronts of the naturals have the "Hitchcock" device. A minor detail, but an extremely important one, is that the ivory is, with great good taste, not bleached, but left its proper colour. The construction of the stand is novel, and will be best understood from the picture.

In 1878, Sir Lawrence (then Mr.) Alma Tadema had constructed for him a grand piano which was designed by himself, and made after the drawings of Mr. G. E. Fox, F.S.A. It was made in the accepted form of the present day—but the design was Byzantine. The decoration consisted of inlays of mahogany, ebony, tortoise-shell, ivory, and mother of pearl, with carvings of oak and ivory, and the work was carried out by Broadwood. Incorporated in the design was a massive seat, the back of which was painted by the artist. The inside of the lid was lined with parchment, and is now covered with the autographs of famous musicians who have played upon the instrument. Further description is unnecessary, as you will see presently what it was like. It must be regarded as altogether unique, and, like the art of its designer and owner, exceptional in its character and distinction.

Two years after, in 1880, was made the famous "Orpheus" piano, the offspring of the genius of Burne-Jones. As I was intimately connected with the inception of this piano, I am able to state that Burne-Jones was largely influenced by William Morris, and had the support and co-operation of the Faulkners. Boldly reverting to the model of 100 years before, Burne-Jones, as I have already described, designed a curve for the bent side, which was an exact repetition of the older curve, although with a greater sweep, owing to the extension of the front, required by the modern compass. The four-legged frame, with its stretcher, was reproduced, and even the loose board in front of the keys, making the front of the instrument rectangular. Several pianos were made by Broadwood of this form. One was the artist's own, perfectly plain, made entirely of oak, and stained all over by his friend Morris such a bright green colour that no one could say æsthetic colours were always dull. Another made for Mr. Muir Mackenzie was of plain oak, and was decorated all over in Gesso work by Miss Faulkner. The "Orpheus" piano was made for his friend and patron Mr. William Graham, and was painted within and without. Round the sides almost in monochrome is depicted, in circular designs, the story of Orpheus. Drawn first in freehand by the artist, they were copied in by his pupils, and finished by himself. The conception of this old-world story is strikingly original. Orpheus, as he enters Hades, is met with a rush of wind, which one seems almost to feel. As he plays his lyre before Jupiter and Juno and makes his request, the God and Goddess are deeply moved, and strong emotion is visible in their faces. As Orpheus is seen rushing through the mists of the nether world, Eurydice lifts her hand to her ear as she catches the familiar sound of his music; while the triple-headed Cerberus, lithe and serpent-like, forgets to bark, and stands agape. Then, with the precious living burden on his back, Orpheus returns. Anxious to behold the form he loves so well, he half turns, and, conscious that with that act Eurydice begins to slip away, he clutches her garments with fearful earnestness. It is too late, the fatal deed is done, and Eurydice is a pale ghost once more. An oblong panel on the end shews the maidens weeping over her body.

The lid of the piano was sent to the Grange, and painted entirely by the artist. On the top is an angel and a poet and a bold arboreal design, amongst which is a scroll from Dante, a poem on spring from the Vita Nuova. Inside Mother Earth is seated on a heap of

gravel surrounded by her good and bad children—an allegory which may be translated into the concord and discord inseparable and immutable in the musical web.

The sounding-board and ironwork are gilded, and on them are painted rose leaves, which appear blown hither and thither as if the pulsations of sound had stirred them. The owner's motto, "Ne oublie," appears in several places. Through the kindness of the present owner, Mrs. Horner, I am able to show to you several views of this beautiful instrument. I will now throw upon the screen views of some of the pianos to which I have just referred, and will add to them the view of a small modern cottage piano, which is the best in form I have been able to find.

I have already given my reason for not dwelling upon the many decorated pianos produced in modern times. Let me say that, so far as form is concerned, most makers are now producing on their own responsibility a few grand pianos which are designed partly upon the old lines, the angular shape and supporting frame of the square legs being adopted. The cottage piano remains much as it was, and usually turns its back to the public, sheltered behind the curtains with which kindly feminine hands drape its rearward. I venture to think that the small Broadwood shewn upon the screen is an exception, and could without much effort be made a thing of beauty. Upon the question of how to decorate the case, when you have improved the form, I only throw out a few humble suggestions. In the first place let us try to believe that the dazzling surface of French polish is not beautiful. This belief, if it dies at all, will die hard. You have, perhaps, heard of the American girl with whom this question alone weighed, and who pointed to the piano of her choice with the joyous exclamation, "Look, Ma, how it shines!" If anything should enable us to avoid this it is the practice which obtains with some of making a dazzling surface, like carriage varnish—a surface, which, when once chipped or injured, cannot be patched up again. To dull wax polish there can be no objection. There is, however, no surface like that which is left from the finest glasspaper, and if you employ hand-carving—and why not do so—the carvings should be left from the chisel. Quiet inlays of wood have a beautiful effect. Ormolu, if not overdone, is suitable in many cases, and might we not with advantage revert to the plaques and medallions of the eighteenth century? Some makers have already copied the beautiful strap hinges of brass-work, and much more might be done in this direction.

But I feel that the art of painting is most neglected in the piano. We need not wait for a genius like him whose work we have admired to-night to give us the creation of his inventive skill. There is plenty of good work suitable for copying, and there are amongst us students and artists who might employ their talent in this direction usefully and profitably. The panels of the cottage piano might be painted in the way that Angelica Kauffmann painted the panels of cabinets, while the surface of the grand piano offers much scope for such decorative treatment.

Our hope for the future lies in a faithful adherence to the principles of the Society which has done me the honour to ask me to read the paper. Our hope lies in the personal skill, the patience, and the genius of the ordinary handicraftsman, and in the recognition of the truth that the necessary complement to decoration is fine and meritorious workmanship. May the day never come when we shall under-value the work of the human hand, and the charm which skilled and intelligent handicraft always carries. A great artist, if he were reported correctly in the daily paper, said last November:—

"In these days, with the increase of people, we need great repetition of artistic things, and these can be obtained sufficiently only by machinery. A copper vase, which it takes three days for a man to hammer out by hand, is not more artistic than one made by machinery in half a day. The sculptor will one day do much of his work by mechanical aid. Antiquity is largely a matter of dust and varnish. We need not cling to the antique. A Gothic window with little panes reflects only the deficiencies of a past age. They would not have had Gothic windows then if they could have had our windows."

I am thankful to believe that such opinions are not widespread. At Doulton's pottery you may see among all modern appliances the potter seated at his wheel as potters sat thousands of years ago, and creating shapes full of charm and beauty such as only the human hand can make—for nothing has ever taken the place of the human hand at the potter's wheel, and never will. So long as we recognise the principles I uphold, we shall never be in sympathy with ruthless restoration in the realm of architecture, nor believe that the crude and raw figures newly put in the facade of the western front of a famous

cathedral are as good as the old. Insensibly I have wandered in my last words once more into the region of architecture, and the distinguished architect who occupies the chair will, I am sure, be the first to forgive me. In 1896, Dr. Stubbs, Dean of Ely, appealed for funds to restore the exterior of the Lady Chapel of his cathedral. In his letter to *The Times* he used words which are so true, and bear so closely on our subject that I cannot refrain from quoting them, and leaving them with you. He says :—

" There is no intention on the part of the Chapter to attempt a ' restoration ' of the interior of the Chapel. They are well aware that is an impossibility. It is said that Welby Pugin once estimated the probable cost of the restoration of the interior of this chapel, with its marvellous arcade of canopied niches covered with the richest profusion of sculptured work at £100,000. But even the provision of that large sum would not make the work possible. There does not exist probably in Europe to-day an artist in stone who could be trusted to repair this defaced sculpture of Alan de Walsingham's craftsmen. For such an artist we must wait for an age when once more art has become not only the expression of a workman's joy in his work, but also the expression of a man of genius who pours into his art, life, conscience, aud labour, as a sacrificial act of devotion to the King in His beauty."

The following letter from Mr. HALSEY RICARDO, was read by the CHAIRMAN :—

" Unless I have been anticipated by the paper, I wish to put it to the manufacturers of pianofortes whether the time has not now come for them to consider the propriety of constructing *square* grand pianofortes. The present length and shape of the " tail " piano is already found to be a difficulty. A very large number of people, who require a grand piano, and to whom the cottage piano is not a substitute, live in houses, or flats, where the reception-rooms are not big enough to admit a concert-grand mainly on account of its size but partly also on account of its intractable shape. In any room—no matter how large—there are not many places, having due regard to the lighting (by daylight), &c., where the piano can be stood, and in most rooms it is a terrible obstruction. The size of its mouth and the required number of its teeth, make its present width, I take it, an irreducible minimum ; and I observe on the part of manufacturers a kind of agony of effort to shorten its tail in order to make it more accommodating to the restrictions of the room in which it will have to stand. The effect of these efforts is increasingly to disfigure its appearance ; it gets lumpier every day ; it has the size without the handiness of an African elephant and the elegance of a mammoth toad. Is it beyond the wit and ingenuity of the manufacturer to pack the works of a piano into a box say six feet long by three feet six inches wide, with the keyboard, not necessarily in the centre, in the longside? Such a rectangular shape would find a place far more easily amongst the other necessary furniture of the room ; and would, I think, be more easy to treat decoratively.

We have to remember, moreover, that whilst the manufacturer is shortening his tail piano all he knows —the pianist is not now content to play upon it merely with his hands, he also insists on playing upon it with his feet ; and therefore to the length of the piano has to be added the extra encroachment of the mechanical arrangement he affixes to the key-board. Whether all this blaze and riot of sound won't lead us in the near future to get our music by the milder method of the (improved) phonograph, time will perhaps shew : if so we shall recover the 25 per cent. of our drawing-room floor space now arrogated by the ponderous piano, filched from our comfort and devoted to the disfigurement of our rooms ; meanwhile, if no home is to be complete without a piano, let us at least have a presentable tyrant, instead of an awkward monster."

DISCUSSION.

The CHAIRMAN said that Mr. Dale's paper contained many very valuable hints on a subject which commended itself to everyone who was musically inclined, and who felt that too much attention could not be bestowed upon an instrument from which so much pleasure was derived, and that it ought to appeal not only to one sense, but to the other senses as well. The author had commenced his paper with a very sad admission—that, by common consent, the modern piano was not an artistic object. There never, surely, could have been a time, except the present, when anyone talking of such an instrument as the piano would have made such an admission ! It was only at the present time that we were content to shrug our shoulders, and sigh, and give up the thing as hopeless. In the earlier days, from the examples they had seen, pianos, so far from being what Mr. Ricardo called disfigurements and encumbrances to a room, were ornaments, and beautiful pieces of furniture, pleasing to the eye as well as to the ear. In those days it was not necessary to call in an artist from outside to design the cases, for the workmen themselves knew how to make them beautiful. They had traditions as to certain shapes to which they conformed, and that artistic sense which inspired all good workmen, the result being that the instrument was beautiful, and pleasing to all the senses. One great difficulty now-a-days was the enormous width necessitated by the great compass. Anyone who had designed a piano—as he had had the good fortune to be called upon to

do—would know how difficult it was to get a graceful shape when the proportion of the width to the length was so much greater than it used to be in the old days of the harpsichord. One would have thought that the compass which sufficed for Bach, Handel, and Beethoven, would have been enough for all time; but he supposed that great width must be accepted as one of the conditions of the present day; and the designer must necessarily conform his design to the conditions of the thing which he had to make beautiful. Fortunately, the piano — even the worst modern ones — had preserved its old harp shape; indeed, it was nothing but a harp laid on its side and played by mechanical means instead of with the fingers. If, as had been anticipated in Mr. Ricardo's communication, the piano were to grow more and more stumpy—shorter in proportion to its length—it would, perhaps, be better to revert to the square grand. Another suggestion which had occurred to him was to set the grand piano upright. The old square grands had lost their harp shape, but why should not the harp-shaped grand be set tail-end upwards? In a museum at Amsterdam to his surprise he once came across a piano of that form. It was an ordinary grand piano with its toe in the air, finished with a sort of scroll, and played upon by the person sitting facing it, as in the case of the cottage piano. He did not known whether there would be any difficulty in making a grand piano in that form. On that point he should like to hear something from those experts in the trade who were present. He could not understand why all modern pianos were put into those hideous rosewood cases which made such ugly black blots in a room, reminding one of Mrs. Ramsbotham's description of old masters she saw in some foreign gallery—when she said she could not see much in them, but they were very black and shone beautifully! Rosewood cases were certainly a disfigurement to a room, and absorbed a good deal of light. The old mahogany cases of sixty or seventy years ago admitted of much more artistic treatment. He was sure those present had been interested in Mr. Dale's interesting paper; and he hoped there would be some expression of opinion from gentlemen in the trade as to the manufacture of pianos and what could be done with them. He trusted that the paper and the discussion which was about to follow would have the effect of arousing attention to the necessity of making these instruments —as pieces of furniture which could either spoil or adorn a room—not only musical to the ear but also beautiful to the eye.

Mr. GEORGE ROSE (Broadwood's) being called upon, said, that as the Chairman had appealed to pianoforte makers, he would attempt to answer one or two points that had been raised. Mr. Dale had asked, Why is the pianoforte externally the thing we see it? The simple answer to that was that the pianoforte was what the makers found they were able to sell. If the pianoforte maker were to work upon the lines Mr. Dale had suggested, he would be utterly unable to pay his way. In saying that he only wished to lead up to what, he thought, was fairly obvious, and which throughout his life he had found to be true, that any advance or improvement in the decoration or artistic beauty of articles of everyday use, must come from those who gradually formed the taste of the nation. If in some respects we had advanced in our ideas of what was the proper thing upon early Victorian days, it was solely on account of the work, and the constant thought and care of those, who, like the Chairman, had led the ideas of the nation in the proper road. It was very difficult indeed for the manufacturers to carry out the ideas which Mr. Dale and the Chairman had so ably put before them. If their clients could only be educated, the manufacturers would be only too glad to make what they knew to be things of beauty. It was some years since the Chairman had designed the instrument which had been shown upon the screen, and which, in his opinion—with all dne respect to Sheraton—was a far more beautiful object than the design of that very eminent cabinetmaker who, especially in the later part of his career, quite frequently went very wrong in some of his designs. It was strange that the instrument Mr. Jackson had designed, which had been exhibited on many occasions, and was known to so many in London, had absolutely never been copied. The reason, surely, was not far to seek. Though we were constantly talking about education in art, as in other things, the public were not yet able to appreciate always what was really beautiful. It was no use asking why the piano was always made of rosewood, and polished like a boot. It was simply because the public wanted it, and would not buy if it were made of anything else. All his life he had had befor him the beautiful examples Mr. Dale had shown, and many others, yet he had found it impossible to get the ordinary customer to accept them. There is a discerning class of people, but the ordinary client would say,—"Yes, it is very nice, indeed," but would pass good design by. One direction in which improvement might well be made was in that of simplicity. Personally he thought the proportions and the lines of a pianoforte were more important than any other attribute of the design. If the Chairman and other eminent architects would only from time to time—as some of them had done—turn their attention to the decoration of that much-abused article of every-day use, the pianoforte, we should, doubtless, in time arrive at something more beautiful. An improvement had, indeed, already taken place in the taste of the public, and it had become possible, recently, to use better and simpler designs for stock models. The design last shown by Mr. Dale, as a good modern example, was produced by the eminent decorator, Mr. Charles C. Allom, for his own use, some years ago, and is, to-day, being largely used and often copied. With regard to the questions as to the shape of the grand pianoforte, and the suggestion

that it might be made vertical, the idea might, doubtless, be carried out, for the clavicitherium, or upright spinet, a very rare instrument, was of this form. As to reviving the square piano, Mr. C. R. Ashbee had designed one a short time ago, and had one in hand for a client at the present time. As the Chairman had said, the pianoforte is a recumbent harp, and that is the reason it naturally takes the form we usually see. With regard to the Sheraton design he ventured to differ from Mr. Dale as to the legs. In many instances of Sheraton's work there was much to lead one to believe that those bulky legs were really his own design, although not to the original drawing. In conclusion, unless it were done with the greatest care it would not be wise to sprinkle the modern piano all over with medallions as Sheraton had done.

Mr. H. H. STATHAM desired to emphasise a point which the author had not forgotten—that the pianoforte was, in the first instance, a musical instrument; but he felt a little jealous, sometimes, of the idea of making it too much a vehicle for ornament, which he thought should be subservient to its original use. He spoke as a musical man as well as one interested in art. When a friend asked him to try a piano, he ran his fingers over the key-board, and if it was satisfactory he did not at the moment think much of the design. The highly-ornamented old stringed instruments to be seen at South Kensington were very incomplete, and very little music could be got from them; but when one came to Stradivarius and Amati, it would be seen that their violins were of the best possible shape for the production of the required sound, and there was but a very severe ornament and nothing else. Such instruments, he maintained, were works of art; they had the beauty of fitness, such as he thought should be aimed at in the main in the case of the piano. There might be exceptional instances where one was inclined to spend a large sum in making a piano a specially beautiful object; but in general what had to be looked to in the making of a piano, as Mr. Rose suggested, was the shape, which arose naturally out of the construction. Mr. Dale was quite right in his references to architecture. What was wanted were fine mouldings and right proportions for expressing construction. The greatest care should be taken in inserting anything, in the shape of added ornament, which at all checked the vibrating power of the instrument. Personally he should be very shy of putting porcelain plaques, or anything of that sort, into a piano; and he rather took fright at the large brass strap hinges, referred to by the author, which, he thought, might rather tend to spoil the tone of the piano. The material which was wanted to surround the strings was that wood which most harmonised with and reinforced the sound. He did not understand why the author objected to the modern position of the pedals, namely in the middle of the instrument. That, surely, was a question of convenience, and was where the player wanted them, and not, as was formerly the case, fixed to the legs. Returning to the square shape of piano, he should have liked to hear something from Mr. Rose as to the length of the strings. If the bass strings were shortened the pitch must be obtained by thickening them, but that would not produce the same tone. To get the finest tone out of a grand long bass strings were necessary. A long-tailed piano, therefore, was really the finest instrument. Short pianos, which were so much disliked on account of their appearance, he objected to on musical grounds, because there was less uniformity and volume of tone. The shape of the grand arose, he thought, naturally out of its construction and, therefore, artistically it was correct. He had seen one of the square pianos designed by Mr. C. R. Ashbee to which Mr. Rose had referred. It was not the old form of square piano with the key-board at the side, but an enormous square thing with the keyboard at one end. It seemed to him a clumsy thing, and calculated to fill up a room much more than the ordinary type of grand piano. He should like to say one word with regard to the key-board. He deprecated any sort of artistic tampering with the black and white keys. One sometimes heard of people with æsthetic tastes having the black keys white and *vice-versâ*, or having inlays on the black keys. But in process of time that might produce a little roughness on the surface of the key which would injure the touch; and the eye also was apt to be misled. Black and white made a very strong contrast, and it was undoubtedly best for the player. It fell in, too, with the principle for which he had been contending—that no ornamentation should be applied which, in any way, interfered with the real use of a pianoforte as a musical instrument.

Mr. HUGH STANNUS, desired to express his thanks to Mr. Dale for his interesting paper. The author, he observed, had spoken of "artistic treatment," and not merely of artistic form, or artistic decoration. The word "treatment" covered both: first, the form of the case, and, secondly, the decoration of that form. People generally seemed to think that a piano was artistically treated when an ugly form was decorated without improving the curves of the lid. Looking at the drawing of the case which had been shown, it would be seen that while the decoration was charming, the curve of the lid—which approached a parabola, was not really a parabola—but exceedingly ugly. As the octaves go down, the strings doubled in length theoretically. It was that doubling, while the distance between the normals remained the same, which produced that most beautiful of all mathematical curves, the parabola, which should be preserved. Then came the decoration of that form, and this opened a very wide field with which it was impossible for him to attempt to deal. Speaking generally, he would like to put a gloss on the word "artistic" as used by Mr. Dale. It meant, he supposed, the

following of certain rules agreed upon by masters of that art. If that were the real definition, it followed that the artistic treatment of a piano-case should be (firstly) suitable to the material, and the material being wood, because of its vibratory qualities, it would obviously be wrong to introduce details which imitated the architecture of stone. The case should (secondly) cover, but not disguise, the mechanism. There were three parts by which the sound was produced, namely, the keys, the hammers, and the strings, and any case, to be artistic, should recognise those three elements. He had never seen a piano which was completely satisafctory in that respect. The case should (thirdly) assist and not impede the tone. Mr. Statham, an amateur musician of admittedly very high capacity, had dealt with that subject, and he need not therefore enter into it. The less metal and the less non-vibratory material put on a piano the better. He had seen piano cases literally overladen with ormulu, which would spoil the tone. Although it might be a very beautiful thing to look at, the piano was, after all, a musical instrument, and not a peg upon which to hang decorative treatment. A fourth point which must not be lost sight of was the fact that the case must permit of accessibility to the working mechanism. A fifth point was that the piano should be constructed so as to occupy as small a space as possible consistent with its use. There were, he thought, great possibilities in the old upright form in which the harp-shape was placed vertically. It might be made so as to give a 10 feet string from floor to ceiling, thereby necessitating very little loading with copper wire in order to get the deep bass, certainly not so much loading as was necessary in the case of the over-strung cottage piano. A sixth point was that no one, so far as he knew, had ever fairly and honestly treated the desk. Too often it was packed away in a dodgy manner, as though one were ashamed of it. Surely the desk was a part of the design, and the artist who had any sympathy with the instrument would take care that it was properly treated. It was those difficulties of treatment which tried the artist, and when difficulties were turned into triumphs, one felt that a true artist was at work on the instrument. Seventhly, he had seen the lights arranged in a most dangerous manner at the corners. The pedals were another point well worthy of consideration. There was plenty of room for improvement in the lid. He regretted the absence of enterprise in the matter of design for cases. After making two piano cases, one of which was thought successful, he felt so strongly that there was an opportunity of further development in the application of scientific principles which had never yet been properly applied to grand pianoforte designs, that he offered to give one of the leading London manufacturers a design for a grand piano to send to an Exhibition which was coming on in the course of a couple of years, but the maker would not accept his offer; and the result was that the design of an American firm was considered the best. Such papers as this one would draw the attention of the public to the question, and there would be hope of improvement.

The CHAIRMAN said he was sure he could speak for all in expressing their thanks to Mr. Dale for the extremely interesting paper which he had read, and also for the illustrations on the screen which they had all so much enjoyed.

The resolution was carried unanimously.

Mr. DALE said he was greatly obliged for the kind expression of thanks which had been accorded him, and also to those gentlemen who had taken part in the discussion and expressed their opinions so freely. At that late hour he could not comment on their remarks in detail, but would merely thank them very heartily for their kind criticisms, and their kind reception of his paper.

TENTH ORDINARY MEETING.

Wednesday, February 13th, 1907; A. A. CAMPBELL SWINTON, M.Inst.C.E., M.I.E.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Foster, Edward, Irwin, Montego Bay P.O., Jamaica, British West Indies.

Gröne, H. Dawson, Inspectorate-General of Customs, Peking, China.

O'Brien, Lieut.-Colonel J., 4, Atherstone-terrace, Gloucester-road, S.W.

Scott, John Gray, Tramways Office, Hong Kong, China.

Sen, Baikunt Nath, Saidabad, Khagra P.O., Murshedabad District, India.

Treble, Mrs. Lillian Massey, Toronto, Canada.

The following candidates were balloted for and duly elected members of the Society:—

Fazl, Shaikh Abul, M.A., LL.D., Jullundher City, Punjab, India.

Green, George Arthur, Public Works Department, Poona, India.

Hanton, Samson Baskcomb, Boys' High School, Rondebosch, Cape Colony, South Africa.

Hartshorne, William Davis, Methuen, Massachussetts, U.S.A.

Hough, Warwick M., 902, Rialto-building, St. Louis, Missouri, U.S.A.

Litten, John George, F.S.A.A., 241, Pitt-street, Sydney, New South Wales, Australia.

Naftel, Cecil Oakley, 20, Eastcheap, E.C.

The paper read was—

MOTOR OMNIBUSES.

By Lord Montagu of Beaulieu.

Less than two years ago the motor omnibus was looked upon as hardly a serious factor in reference to public locomotion. Most traffic experts shook their heads and the chairmen and managers of the great railway companies smiled, when one talked to them about motor omnibus competition, or the linking up of railway stations with outlying country districts by means of mechanically propelled road vehicles as an alternative to building branch or light railways. Two years ago none of the chief omnibus companies of London had any mechanically propelled 'buses running (though a small company were just starting on the Edgware-road route), and a large proportion of their boards and their shareholders were inclined to regard the motor 'bus as an object either not worth serious consideration, or to be avoided and snubbed. Since then to the present moment there has been a rapid and remarkable change of public opinion. Only lately railway chairmen have one after the other complained of the competition of motor cars and motor omnibuses as affecting their receipts, while the tramways of the London County Council and other municipalities, and tubes have shewn by a decrease in the number of passengers carried how quickly and seriously the motor 'bus is acquiring the traffic of the tubes and tramways which hitherto they had considered their monopoly. To quote a specific instance, Sir Henry Oakley recently told the shareholders of the "Twopenny Tube," of which he is Chairman, that he would probably have to alter the present fare and charge 1d. for certain short distances, instead of the universal fare of 2d. hitherto in vogue, in consequence of the competition of motor omnibuses. He added that in the last six months 1,000,000 passengers and £17,000 in receipts had been lost, and this he attributed to the competition of the new means of street locomotion. The chairmen of other tubes have also been telling the same tale, while the perfervid utterances of the tramway advocates of the London County Council show how nervous they have become. It is of course inevitable that they should be jealous and openly abuse the motor 'bus, for it is evident that the profits—if any—of the tramways owned by the London County Council are being seriously threatened by the increase of motor 'buses, which can carry a far greater number of passengers for a smaller capital outlay.

I have no intention or wish, however, this evening to enter into current politics, either national or municipal, but locomotion is rapidly becoming a political, or, at any rate, a municipal topic, and totally to avoid the criticism of tramway specialists and their theories is impossible. The effect of the advent of the motor 'bus in London and in some other large towns has been very marked. The recent returns of the London County Council show that the total receipts declined last year by about £40,000, and the amount paid in relief of rates has diminished from £69,000, the maximum in 1901, to nil in 1906. Moreover, it seems to me the more perfect the motor 'bus becomes—no one would assert that it is in any way perfect yet—and the more its admitted drawbacks, such as noisiness, jerkiness, vibration, aud skidding, are remedied, the more formidable rival it will become to every kind of rail or horse traction. Already motor 'buses in London last year carried 184,000,000 passengers, as against 180,000,000 carried by the London County Council trams. Probably, however, taking a broad view, for the time being at any rate, there will be enough traffic in London and other large towns to occupy all and every possible means of conveyance. But if one considers in the case of London the congested character of many of the principal streets, and the utter want of co-ordination in the design of traffic facilities, it is clear that until a London Traffic Board is established, which will contain experts in every form of locomotion, it will be hopeless to think that public traffic facilities in and around the Metropolis can be properly organised or controlled. It is unfortunate, moreover, that the present Government have not seen their way to carry out the recommendations of the Royal Commission on London Traffic, an entirely non-political body, whose report is recognised to be the most up-to-date document on town traffic in the world, who advised the formation of an independent London Traffic Board. Perhaps we may hazard the conjecture that the political pressure of the so-called Progressive party on the London County Council prevents Ministers carrying out what they know would be right in the interests of London, for tramways have been made the sheet anchor of the Progressist programme. I will not say more as I am beginning to enter upon dangerous controversial ground.

A few statistics as to the number of motor 'buses running in London at the present moment may not be out of place. The average

motor 'bus carries 34 people as against 26 by the horse vehicle. A motor 'bus does the work of 1½ horse 'buses. Therefore, a motor 'bus replaces from 12 to 16½ horses per day, reckoning 11 horses per horse 'bus. As to numbers, on the 1st February, about 850 vehicles were licensed and running, a number which shows an increase of about 300 since the 1st August last. On that date there were something like 800 to 900 new 'buses on order, but a number of these, although now constructed, have been disqualified or put back for alteration by the police licensing authorities at Scotland-yard on account of alleged noise or other defects. The number running would otherwise have well exceeded 1,000 by now. To this subject of examination and licensing I will refer later on. There are at the present time, so far as I have been able to gather, from information kindly supplied to me by the principal companies, about 1,000 ordered or constructed but not yet on the roads.

The capital embarked by the various public conveyance companies in motor 'buses, garages, &c., in London, is just about one million, estimating that the average cost of each 'bus is about £700, of which about £600,000 is represented by vehicles actually running on the streets, while the balance is invested in 'buses on order and buildings. The number of men employed by the various companies, including drivers, mechanics, cleaners, attendants, &c., can be safely estimated at about 4,000.

In the country about another million has been invested and the amount is increasing rapidly. Local services controlled by small companies are becoming more common, and are in some places superseding the country carriers. Existing motor 'bus services in London are conveying about 400,000 passengers daily, and it is a startling fact, which I have mentioned already, that during last year the few motor 'buses actually running, averaging not more than 550 for the complete year, carried more human beings than were carried on the various London County Council tram routes in the same period. The capital cost of the latter has already exceeded £6,000,000 sterling. This is a fact which is self-eloquent as to the superior financial prospects of the motor 'bus, showing as it does that the vast capital expenditure necessitated by old-fashioned systems of railed traction compared unfavourably with the smaller outlay necessitated by the self-propelled and mobile motor 'bus. From another point of view it is interesting to reflect that less than two years ago frothy democrats were denouncing all motor vehicles as the luxuries of the rich, and declaring that they would be of no use to the democracy. But the motor omnibuses which convey in London alone 2,500,000 of passengers per week prove that they were wrong. If we add the country passengers we shall be safe in assuming that over 3,000,000 passengers are carried by the public service vehicles of this kind every week.

As regards the daily average takings of motor and horse 'buses, from some confidential figures which some of the companies have courteously sent me, I estimate that the motor 'bus in London earns from £4 10s. to £6 per day, as against the horse 'bus, which averages £2 10s. to £2 15s. Originally the greater earnings of the former might have been attributed to novelty, but now the motor 'bus is one of the common objects on the streets this argument can no longer hold good. The fact is that the motor 'bus carries more passengers in addition to covering more miles per day, so that its earnings are therefore greater than the horse 'bus.

The average distance covered by motor 'buses in London varies from 90 to 120 miles per day. The longest routes covered by these vehicles include Lewisham to Oxford-street, Putney to Bow-bridge (traversing the City), Charing Cross to Richmond, Putney to Gospel Oak, Tufnell-park to Barnes-common, and others. Motor 'buses are now, or will soon be, running into distant suburbs, such as Epping and Barnet on the east and north, while to the west and south their routes go as far as Richmond. Probably in the near future there will be a regular service to all places within 20 miles of London, and in connection with this it should be remembered that the motor 'bus, unlike the train and tram, can convey the business man, clerk, or artisan, from the pavement near his place of work, or wherever he happens to be, to a point if not actually his home, in most cases the road or end of the street in which he lives. It is this conveyance practically from door to door which is one of the most valuable qualities of the motor 'bus. Here the railway, tramway, and tube are equally at a disadvantage. At the present moment at the busy times of the day, the motor 'bus is consequently so popular that the difficulty is to get a seat at all, and even when the new omnibuses now on order are put on the streets, for a long time to come between the hours of 8 and 10 in the morning, and 5 and

8 in the evening, motor 'buses are likely to be overcrowded.

In the matter of mobility the motor 'bus, too, has another advantage over its fixed rail rival, for if it is not wanted on a particular route in the middle of the day it can ply on other routes which may be more profitable, whereas in the case of tramways the cars must go backwards and forward on the same route, being unable to deviate in the slightest from their railed route. For instance, afternoon runs from the suburbs to shopping centres can be organised. Another merit of the motor 'bus is that it can draw up at the kerb to put down or take up passengers. The centre of a muddy street congested with hurrying traffic is not an ideal spot for joining or alighting from a conveyance. Yet in the majority of cases this is the fate of the tram passenger in big towns.

As to the various makes of 'buses I do not propose to enter very largely into mechanical details to-night, but am glad to be able to say that whereas originally most of the public service motor vehicles employed in Great Britain were of foreign make, the majority of the more successful vehicles now in use have been built by English firms. The two main systems in use at present are the ordinary internal combustion engine worked with petrol, and steam, the former vehicles being the most numerous. Although steam ought theoretically to produce superior flexibility, quietness and ease in manœuvring, in everyday practice it seems to be very little, if at all, superior to the internal combustion engine. As to the future there are some who think that electrically propelled 'buses, operated by means of accumulators, will eventually supersede other systems of propulsion. It seems, however, that the perfect accumulator is as far off as ever, though Mr. Edison, as a rule, announces two or three times a year that the problem of supplying electric power in a smaller compass and with less weight has been solved. But there is no evidence as yet that such an accumulator is approaching the commercial stage. Another system which is about to be tried, and of which I can speak more hopefully, is that which is proposed to be used by the Auto-Mixte Omnibus Company. This is a combination of the petrol engine and electricity, the latter being used chiefly as a means of transmission of power, though a few storage batteries are also carried for certain purposes such as starting and assisting up hills. Some experts think that this system or something like it will eventually become universal. The chief problems of to-day are how to reduce noise, and how to provide for extra power for starting and for sudden short hills. These are the difficulties with which the modern engine, whether steam or petrol, has to cope.

There are many special advantages of the motor 'bus which are clearly admitted even by its opponents. But there is one supreme disadvantage to which I must refer, viz., the tendency to skid on any road which is at all of a slippery nature. Skidding may be said to arise not only from the motor 'bus itself, but to a large extent from the shape of the road, and from horse and other refuse left upon it; also from unscientific construction of the road surface. When mechanically-propelled vehicles become the rule and not the exception, roads will doubtless be made concave instead of convex, the concavity being very slight. But the skidding of motor 'buses largely depends also upon good or bad driving. Many motor 'bus drivers are now so experienced that they can handle their 'buses on almost any surface, whether slippery or not, whereas others do not seem to have the knack of so doing. It should also be added that there are many devices which would appear to prevent skidding entirely, but the regulations of the Local Government Board, which are strictly enforced by the police authorities, prevent their application. For instance, although ordinary horse-drawn traffic is allowed to proceed on iron-rimmed wheels, motor traction, if it exceeds eight miles an hour and weighs over a certain tonnage, must have rubber or resilient wheels of some kind. The fifth wheel remedy is probably the simplest device to prevent skidding, but cannot be made much use of on account of this regulation, for to be of any use the metal sides of the fifth wheel should project outwards, and the tire as presented to the road, should be slightly concave instead of flat or convex.

I have referred to other nuisances of motor 'buses, viz., noise, and I think there only remains the third drawback, namely, smell, which I now believe is hardly worth serious notice in this place as it has been practically abated, and the blue hazy smoke which used to follow behind many of the motor 'buses a year ago is now comparatively rare. Over-lubrication is merely a result of faulty design or faulty working, and just as this nuisance has been eliminated in private cars it can be eliminated in motor 'buses.

One of the drawbacks to motor 'bus traction hitherto has been the running costs compared with other forms of public traction. A year ago it may be said that the average cost in London for each motor omnibus was upwards of 11½d. per mile run. From the information which has been recently supplied to me, most of which is confidential, I can assert that the average cost does not exceed 10½d., while in some cases it is lower, 9¼d. being the lowest figure I have seen.

By the courtesy of my friend, Colonel Crompton, I am able to quote from his pamphlet "Modern Motor Vehicles," the figures which he estimates as the cost of running a motor omnibus in London, and in the country:—

London	10·27d. per mile.
Country	12·94d. ,,

and also to give a very interesting Table (see p. 378).

Now the cost of operating tramways, even on a big scale such as is the case in the London County Council system or that of the London United Tramway Company, has been estimated by experts to average 10d. per mile, so there is little if any difference in the cost per mile at the present time, and critics allege that there is a tendency in the case of tramway accounts to provide an inefficient amount for depreciation. But I would add that whereas tramways in their original horse form were established about 60 years ago, and whereas electric and mechanical trams have already been running some twenty years, motor 'buses have hardly been running on our streets for two years in a practical sense. The most economical methods of running have not yet, therefore, been ascertained, and expenses inseparable from new ventures are being incurred, which leads one to think that in the future the working expenses will be still further reduced. Is there even now any other form of public traction which can show as low a cost as 9¼d. a mile?

One of the most important points to be considered in relation to the successful running of motor omnibuses is the question of the training of drivers. A year ago the majority of men were admittedly unskilled in their work, or if skilled had not given satisfaction, as a rule, in their former situations, and had taken to motor 'bus driving as a temporary means of livelihood. Not only were the majority unskilled in mechanics but also in handling of the vehicle and in proceeding through London traffic, the latter an art in itself, which can only be acquired by practice. No one, however, can help being struck with the great improvement in the driving of the 'buses now as compared with a year ago. I was watching a few days ago, during one of the temporary thaws, followed by brief snow falls, which make the streets of London in winter more difficult to travel on than any other surface in the world—the efforts of a man in charge of a motor 'bus passing below my window in Piccadilly, to overcome the skidding of his vehicle and to proceed on his way. At this particular point, the roadway is constructed in a thoroughly unscientific and dangerous manner, as there is a sharp fall towards the south side of Piccadilly, which I estimate at not less than 1 in 15, and this excessive camber tends to cause all vehicles, even horse 'buses, to skid down towards the pavement, when proceeding westward towards Hyde-park Corner. I must honestly say that a driver of ten years' experience could not have handled his vehicle better than did this man and one or two other drivers who had the same difficulties to face. They were cautious, yet bold, and eventually regained complete control of their vehicles on a surface which could only be likened to a butter slide. In each of the many cases I witnessed on that particular day, I saw not a single collision with a street refuge or with any other vehicle, or even with the kerb, a fact which in itself does great credit to the many drivers concerned. This great improvement is largely due to some of the large companies having taken great pains to train their men, but not a little credit is also due to the diligence and interest of the drivers themselves in their work. Not only is a trained man more safe from the public point of view, but in the long run he is a cheaper man from the motor omnibus company's point of view, although he may receive higher wages. To give you some idea of what I mean, I may mention that at one time a certain large and well-known company could not insure their omnibuses against accident with the insurance companies or at Lloyd's even at as high a premium as £1 5s. per week per 'bus, or £65 per annum for each vehicle. The number of wrecked refuges and pillar-boxes, and of shattered lamp-posts, to say nothing of accidents to other vehicles and human beings, were up to a year ago quite formidable. I dare to prophecy that four or five years hence motor 'buses will not only be rapidly superseding every other kind of public service vehicle, but that they will be looked upon rightly as the safest, and be more

noiseless than any form of traction we possess at present. This is a big claim to make, but if so much progress has been made in less than two years, what will be made in double that time in future?

As to the wages of the drivers, they naturally vary in London and the provinces, but the average driver earns from 6s. 6d. to 6s. 10d. per day of nine hours, and about the same when paid by the trip, which is now the commoner method.

In future I think we shall see the motor 'bus used in an increased degree for the purposes of excursions from London into the country. Probably in a short time there will be a number of public vehicles which will take London passengers to race meetings, such as those held at Epsom, Hurst-park, and Sandown, and to river-side resorts, and such places as Richmond-park and Epping Forest. On Saturdays and Sundays there will be, perhaps, longer excursions to Brighton and sea-side resorts, thus enabling many thousands to get a breath of fresh air without the trouble of catching trains to and from a railway station, probably some distance from their home. No doubt, also, we shall soon see excursions for two or three days, or for a week or more, organised by the motor 'bus companies from London or other big centres of population to beautiful parts of Wales, Scotland, or the West of England. These excursions would, I believe, even now be well patronised, though of course there is yet no vehicle specially designed for such long distance runs. But the motor 'bus will certainly be ubiquitous and popular long before the main roads are fit to carry much increased fast and heavy traffic of this nature.

To refer to the employment of motor omnibuses by railways, it has always been somewhat of a surprise to me that, with possibly the exception of the Great Western, they have made no attempt to make much use of them.

Those who have endeavoured to develop their districts by their own motor 'buses have suffered far less in diminution of receipts than those who have allowed others to start services, in fact in many cases they have gained in passenger receipts compared with those railways who have declined to move with the times, or who have allowed prejudice to prevent them making use of the new form of conveyance. Perhaps the most notable instance of progress in the right direction has been that of the Great Western Railway, which already has twenty-four distinct services in connection with its system, varying from facilities for such thickly populated districts as Slough, Windsor and the Thames Valley neighbourhood, to services in the far West of England in sparsely populated parts where the motor 'buses have to make long journeys, and so to speak have to work hard for their living.

Nor are the Great Western stopping here. Next summer they are organising fresh services in Wales, and opening up beautiful routes between Cardiff and Aberystwith and other places in that district. Several other railways have also endeavoured to develop their country districts by the addition of motor 'bus services, such as the North Eastern, the Great Northern of Scotland, while in a minor degree the South Western and Great Eastern have in a half-hearted sort of way, and apparently with little energy, been endeavouring to follow in the footsteps of the more progressive railways.

There are many villages and towns of considerable size which lie at some distance from places on main lines, while on many branch lines the service is difficult to arrange so as to fit in conveniently with main line trains, and communication is consequently bad. Probably too if the truth were known there are but few branch lines on our trunk systems which pay as branch lines, and in many cases it would probably be cheaper for the railway companies to tear up the metals on these branch railways and convert them into motor roads, which could be easily prepared for the purpose. They could then run thereon their own motor 'buses, in addition to making a charge for other cars, instead of continuing the present expensive system which necessitates frequent renewals of sleepers and rails, and signals, the maintenance of station platforms and the wages of station-masters, porters, booking-clerks, and all the staff necessary to operate ordinary railway services. But boards of directors are intensely conservative as a rule, and probably neither they nor the general managers realise at present the possibilities of saving money, and at the same time giving better services which may lie ahead of railways in this direction.

There has been some discussion of late as to whether public service vehicles, such as motor omnibuses, should bear any cost beyond the rates which they pay on any real property which they own or occupy, towards the upkeep of the roads over which they travel. This is a question which is bound to come to the front with increasing force. In the case of tramways the companies have to pay rates not

only on their depôts, but on the strip of the street over which their cars run—in some cases amounting to a considerable sum.

In the case of motor 'buses they are exempt, as are all other vehicles not running upon rails, from paying any contribution as vehicles towards the upkeep of the roads. I am not at all sure that this principle can be defended, for it is obvious that those who use the roads should, as a matter of theory, help to pay for them. The present system is founded, however, upon the assumption that only the surrounding owners and occupiers are interested in the upkeep of the roads or derive any advantage from using them. It is conceivable, to take a possible case, that a motor 'bus company might have a depôt well outside the metropolitan area and pay nothing whatever towards the highway rates, and yet have the use of the London streets for the purpose of earning revenue for their shareholders. This can be fairly described as indefensible in principle, and I cannot help thinking that, in the near future, the motor omnibus companies and all other vehicles, including private vehicles, will have to pay something towards the highway rates as vehicles. Of course, as regards public service carriages, it will mean that the public themselves will have to pay towards the upkeep of roads —for the fares will have to be readjusted to bear the burden. But this is only as it should be. At the present moment millions of people are daily using the roads in town and country alike who do not contribute anything towards the highway rate, while others who use the roads but little, and derive but small advantage from them, have to bear nine-tenths of the burden. It should be remembered that Lord Goschen, whose recent death we all regret, brought in a Wheel and Van Tax when he was Chancellor of the Exchequer. The idea was then rejected, as the political pressure brought to bear upon members of the House of Commons by the owners of carts and waggons was such as to make its passage impossible. Public opinion has, however, advanced a good deal since then, and I can only advise motor-omnibus managers and shareholders to see that if an attempt is made to tax their vehicles, other vehicles are included and made also to pay their share, for all should pay for what all use. The motor 'bus can also claim that it does not cause so much wear or tear to streets or roads as many horse-drawn vehicles, the hammering hoofs of the horses being absent. In towns also the absence of the droppings of sixteen horses per 'bus is also a considerable saving in scavenging, besides the gain in cleanliness and public health. As a matter of room, I may mention that a motor 'bus takes up slightly less room than a horse 'bus, a gain to the traffic of the streets.

I think a word or two should be said as to the much-criticised action of the police in disqualifying motor 'buses on the grounds of noise or other defects. In this matter the Commissioner of the Metropolitan Police has been between the devil and the deep sea. On the one side he has had continued protests and petitions from frontagers whose houses abut on the roads, also from shopkeepers, as to the nuisance arising from the motor 'bus traffic— a nuisance which is not only prevalent during the day when the volume of other sounds somewhat diminishes its particular noise, but also at night when the jaded brain worker is seeking repose. On the other hand the Commissioner has been confronted with promises, or at any rate understandings which have been arrived at between the motor 'bus owners and his officials as to types which were considered by them at one time to be perfectly fit to run on the streets. Those who blame Sir Edward Henry should remember that the omnibus which was considered quiet enough to pass Scotland-yard tests last year has not a chance of passing to-day because neither the public nor Parliament would allow it. The motor 'bus proprietors, on the other hand, are declaring that Scotland-yard has broken its promises and has rejected types which were then passed as inoffensive to the ears of Londoners. The question is indeed a difficult one. I know there have been cases of hardship for certain motor 'bus companies, and yet I cannot in another sense blame Sir Edward Henry for the levelling up of his standard — though in some instances I think more notice might have been given to the companies concerned, and that hopes ought not to have been held out originally that certain types would be certainly admitted to run, in view of the uncertainty of the public attitude on this question.

In this connection one of the greatest difficulties arises from the human factor. There is, curiously enough, no machine by which noise can be measured for any prolonged period, for though the gramophone and phonograph will accurately register for a few seconds or minutes certain well-defined sounds, the intensity and volume of noise

has yet to be measured by a scientific instrument. I may mention that at the present time I am occupied with a friend who is assisting me in endeavouring to produce such an apparatus which will be applicable for measuring noises, whether in railways, streets, or anywhere else, where a long and accurate record of noise is required. But the only testing apparatus used to-day for motor 'buses is the ear of the licensing inspector. If this individual happens to have a cold in his head he probably does not notice slight grinding in the gear to anything like the same extent as he would in his normal state of health. If again he has home or official worries, or is suffering from nervous strain of any kind, a noise which in reality may be comparatively small will appear to him large, and jar upon his nerves, probably causing him to disqualify what another and happier inspector possessing better nerves, would pass. It is true that there is an appeal to the Assistant Commissioner and some others, but naturally courts of appeal do not like upsetting the judgment of trusted officials, and it is no wonder that in the majority of cases those appealed to decline to alter a decision already arrived at.

Rapid, cheap and efficient conveyances for the public use, whether in the cities or in the country, are a most important factor in the well-being of a nation. Locomotion enters so largely into the problems of civilised life, and into the development of a nation's prosperity, that I may, therefore, be pardoned if, in conclusion, I depart from the question of mere facts and figures, and ask you to follow me for a moment into a field which is social and political. It is but a truism to say that the great evils arising from congested humanity in cities can be largely solved by cheaper and swifter locomotion. The man working whether with brain or hand, does not nowadays count the distance from his home to his work in miles, but in the minutes taken on the journey. Congested areas and high rents depend, to a large extent, therefore, upon insufficient and slow public locomotion, for they are only crowded on account of the propinquity of the situation to lucrative work. If, say, a clerk in the City could make his home at a spot 20 miles out of London, to which there was a rapid and punctual service of motor 'buses, taking him from his home to his business house in the same time as it now takes to get to either Brixton or Ilford by train and horse 'bus, providing that the new locomotion is equally cheap and punctual, he would tend to go to the new spot where rents would be certainly cheaper, where there was the possibility of a garden, and where the wife and family could enjoy more sun and fresher air.

Crowded areas in towns have arisen not so much on account of the gregarious tendency of mankind, but on account of insufficient traffic facilities. To be close to his work is the aim of every worker. It means not only more time at home in the evening, but also what should not be forgotten, a longer sleep in the morning. At the present moment the time taken to reach the suburbs of London is ridiculous compared with their distance. None of the existing railways, tramways, or tubes, have altered this to any large extent of late for they run on fixed lines, and unless the place of business is close to the one station and home close to the other, much time is wasted, and a house nearer the centre is more desirable.

As regards the country we have exactly opposite conditions to the town. Producers are in this case languishing, because there are no consumers near at hand, while dullness and consequent apathy in every-day life becomes one of the traits of the countryman as compared with the townsman, because the former has to stay always in one place. Communication with the neighbouring large town is often difficult and expensive, and farmers complain that they cannot get their produce to market sufficiently cheaply or quickly, at the same time as the town dweller complains that his perishable foodstuffs are stale and expensive. All these difficulties could be removed by better inter-communication, and mechanically-propelled vehicles at the service of the public, which, running upon the road, could convey food or other necessaries or luxuries from producer to consumer direct, would be both profitable to the owners and would do much to solve many of our land and population problems. Better locomotion must increase the well-being of the race, and motor 'buses can and will do much in this direction.

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought it would be admitted that the most striking figures Lord Montagu had given in his paper were those comparing the London motor omnibuses and the London County Council tramways. The author had put forward a statement which was not exaggerated, in fact, he thought it could have been made even stronger, that at the present time the motor omnibuses of London, with a capital expenditure of about one

million sterling, were carrying a larger number of passengers than the London County Council tramways with an expenditure of six million sterling. He understood it was proposed by the London County Council to spend five millions more. He would suggest that, before those further five millions were expended, due consideration should be given to the possibility that it might be better to save a large portion of that sum and apply the remainder to making improvements, not only in the width and corners of streets, but also more especially to the surface of the roads, thus enabling the motor omnibuses to carry the population more smoothly and with less noise. The author had been kind enough to refer to him in connection with tramway statistics. So far as provincial tramways were concerned he could in many cases give figures that would be reliable; but he confessed that when he came to deal with the figures of the London County Council he should be sorry to express his entire feelings. Of course, it was very easy to show a profit on any business if a great portion of the expenses were charged to other accounts, and that was, he was afraid, what the London County Council did. In May last, Lord Welby, the chairman of the Finance Committee of the London County Council, after admitting that some £40,000 to £50,000 would be required to make up the amount required for renewals in the past two or three years to a standard of 1d. a car mile, which was the then standard of the London County Council, went on further to admit that that sum of 1d. was in itself too low a figure. Moreover, it was interesting to note that the Comptroller of the London County Council, in evidence which he gave officially last year before the Select Committee of the House of Lords, based his estimates on an allowance not of 1d., but on 1½d. per car mile. Thus it would be seen that the London County Council managed to show no loss on their tramways by the simple plan of allowing for renewals a sum which the chairman of their Finance Committee admitted was too small, and which was in fact 33⅓ per cent. less than the figure put forward as a proper one by the Comptroller of the Council. But was even 1½d. sufficient? Turning to Glasgow, whose municipal enterprise was always held up to admiration by the votaries of municipal trading, something startling would be seen, for Glasgow allowed for renewals and depreciation a figure which approximated to 3d. per car mile, just double that put forward by the Comptroller of the County Council. The Glasgow trams had been running for a long time, and they had experience which the London County Council had not, and if, therefore, the figure of 3d. per car mile was allowed, the London County Council's so-called profit of £4,000 a year immediately became a loss of £120,000 a year. Lord Montagu had given some very interesting figures, taken from a paper read by Colonel Crompton at the Institution of Civil Engineers, in regard to the costs of running motor omnibuses in London and the country. So far as London was concerned, he (the speaker) was in somewhat of a difficulty, because there was severe competition. He, therefore, did not wish to say more than that he thought Colonel Crompton's figures were approximately correct. As far as the country was concerned, he happened to be in a somewhat freer condition, because at Bath (where he was a director of the tramway company, which had commenced running motor omnibuses in connection with the tramway) there was no competition, and there was no reason why he should not give the actual figures. Last year the company ran their motor omnibuses, exclusive of depreciation and of general management, but inclusive of everything else, for 8·56d. per car mile. It was an open point what should be allowed for depreciation, but he would assume Colonel Crompton's figure as correct, namely 20 per cent. The reason supervision was excluded from the figure of 8·56d. was simply because the company added the motor 'buses on to the tramways which already existed, and they did not add to their management expenses; but again he would take the figures of Colonel Crompton, ·75d. If those figures were added together, the total cost of running the 'buses was just about 1d. less per mile than the figure given in Colonel Crompton's table; and it must also be borne in mind that Bath was a very hilly district, and the conditions of running were very severe. With regard to the question of the rating of omnibuses, from a strictly legal point of view the rating of any movable object was absurd. Only things attached to property could be rated. It was contrary to all legal ideas to rate movable objects, but motor omnibuses might be taxed, which was another way of getting at the same result. He agreed up to a certain point with the author of the paper, that there were reasons for inquiring why a tramway should have to pay (although it must be borne in mind it did not pay anything upon its rolling stock, which was also the case with railways) and a motor 'bus company should not pay anything. That sounded plausible at first sight, but he would put the matter in another way. Motor omnibuses, as they were at present allowed to run by the Local Government Board, had to be fitted with indiarubber tyres; and, at any rate, so far as asphalte, wood paving, or stone sets were concerned, the 'buses did not wear the roads to any appreciable extent. The road was worn out by vehicles with iron tyres, and by the horses with heavy hoofs, and he thought, therefore, it would be grossly unfair to tax new and modern motor vehicles which did not wear the road, and leave untaxed the older vehicles which did. In fact, he thought himself the proper basis would be to begin by taxing all the vehicles that wore the road; and if that was adopted there would soon be none of the old sort left. He thought, however, it was probable there would be something of the nature of taxes applied to motor vehicles. He would further point out that those vehicles were the carriages, not of the rich, but of the moderately well-to-do and the

poor, and although it might be termed taxing the companies, the people who would eventually pay the cost were the passengers. It was, therefore, a doubtful question whether it would be worth while to go into the question of taxing public vehicles because of the very great difficulties which existed. Unless the continental plan were adopted in London, of a system of gates, complicated by a system of registration, he did not know how the taxes could be levied.

Mr. T. CLARKSON, after congratulating the author on his fresh and suggestive paper upon a vital subject, thought it would be agreed by all that the running of a motor 'bus service was the most severe kind of work to which any motor vehicles could be put, the work of private motor cars and commercial vehicles not bearing any comparison with it. One of the essential difficulties of the problem was the paradoxical nature of the service. In the first place, it was continuous, *i.e.*, the cars had to be in service 18 or 19 hours a day, and in most cases they were not permitted to get cool. Another difficulty was the intermittent character of the service, owing to the large number of stops and starts which had to be made; while another difficulty was the rough treatment the 'buses obtained, the rough roads over which they had to run and, rough garage facilities. In spite of these drawbacks, they were required to give a smooth and silent service free from vibration. The importance of garage facilitities from a financial point of view were not yet sufficiently recognised. Military authorities recognised that, in the late war with Russia, the Japanese owed as much to their medical and hospital equipments in replacing the wounded men early into the field as to the efficiency of their battalions; and it was important to recognise that garages should be made as highly effective as possible in order to put quickly out on the road cars that had been in the wars. At the present time, lubricating oil was not used so effectually as it should be. He knew of some 'buses which used 1½ gallons a day, while others used 2½ gallons, but he saw no reason why a 'bus running under London conditions should not be effectively lubricated with ½ gallon a day. If such a saving were effected, in a service of 100 cars the annual saving would be £3,000. In order to maintain a regular service a certain number of cars must be kept in reserve, in his opinion, one in five or six in London, and one in seven or eight in the country, being sufficient. With a reserve of one in seven, at Torquay, the lost mileage for the first year of service was 3 per cent., for the second year 1 per cent., and the last year ·98 per cent., a record which had not been approached by any other motor 'bus company, either in town or country. With regard to the question of capital outlay, £5,000 was spent on the 'buses at Torquay; and during the three years they had paid dividends of 7½ per cent., and put to reserve a sum equal to half the capital. Unfortunately, however, the 'buses came too late, because a tramway scheme was too far advanced to be abandoned. £80,000 had been spent on the tramways during the last four years, and they had not yet carried a single passenger, while over 1½ million passengers had been carried by the motor 'buses. Although it was quite a small service, the facts he had mentioned emphasised the importance of the financial point. Dealing with the question of steam versus petrol, it must be borne in mind that the thermal efficiency of the internal combustion engine had practically been reached. He had recently been studying Mr. Dugald Clerk's paper, which was shortly to be read before the Institution of Civil Engineers, on the limits of thermal efficiency in the internal combustion engine, and he found there was not much chance of getting a higher mileage per gallon out of the internal combustion engine than was already obtained. By the employment, however, of more highly-superheated steam, under conditions approximate to the internal combustion engine, it was possible to increase the efficiency of the steam engine fully 50 per cent. more than anything at present on the road. The temperature at which steam was now being used, about 700 degrees, was gradually being raised; and he had recently made tests which went to show that none of the steam cars on the road at present were giving as much as 60 per cent. of what would be obtained in the future. Like the North Pole, the perfect motor 'bus had not yet been reached. In addition to the difficulties of the road, difficulties connected with the Scotland Yard authorities had to be faced, which had directly and indirectly involved the pioneers in a blizzard of unprecedented vigour; but he did not think it would be many years before the great superiority of motor 'buses over every form of mechanical traction upon the roads for the work they had to do would be admitted on all hands.

Sir BOVERTON REDWOOD desired to express his high sense of the value of the paper as a contribution to the literature of the subject, and thought the Society was to be congratulated upon having obtained so interesting a paper. The author was well qualified to discuss various aspects of the subject, but in addition he was in the peculiarly fortunate position of being able to speak freely and fearlessly where others equally well-informed might perforce have to remain silent. He hoped in the interests of the ratepayers some of the remarkable statements which had been so graphically set forth would be considered by tramway enthusiasts before further recommendations were made for increased expenditure on that system of locomotion.

Captain SWINTON, L.C.C., after stating that he was not, as he was supposed to be, the great opponent of tramcars in London, and that he had no personal or financial interest in motor 'buses, said he had taken rather a strong view on the subject of the expenditure of the County Council on their tramway system, and the way in which the so-called profits had been put

before the people. He did that with a high sense of responsibility, because he did not believe in those profits. It had already been stated that the County Council did not place a sufficient sum against depreciation and renewals, but he held that what wrecked the figures of the London County Council was the way in which the expenditure on street widenings for tramway purposes was dealt with. The tramways of the London County Council stood in the books of the Council as having had £4,700,000 expended upon them, but, in addition, four millions of money had been spent in widening streets along which the tramways ran. He was prepared to state that, if the tramways had not existed under no circumstances would more than two millions of that money have been spent, and of the remaining two millions up to the present time only £152,000 had been put against the tramway system, while a further £200,000 was to be charged against it, so that the people of London were paying £1,700,000 which they would not have had to pay if there had been no question of running tramways. About a year ago he read a paper before the Society on the question of London Traffic, in which he contended that most of the problems which had to be dealt with in London depended, to a very great extent, on the power of both men and the produce of their labour being carried about London cheaply and quickly. The tramcar had great advantages. When it was going fast and when it was not impeded it was undoubtedly the most comfortable method of travel imaginable, especially to passengers on the top; but from personal experience he had come to the conclusion that, for fast travelling, it was necessary to get on a motor 'bus and not on a tram car. He strongly held that all forms of competition were required in London, in fact, as a ratepayer, he did not think too much competition could exist, as long as it was co-ordinated for the advantage of everybody. If the London County Conncil had had power to run motor omnibuses, it was perfectly certain they would be running them all over London at the present time; but although they started to run 'buses across the bridges, as a part of their municipal trading, they were stopped. If it had not been for that, so much would not have been heard about tram cars; but the controlling body of the moment having embarked on such an enormously costly system of locomotion, they looked upon every other form of traffic as an enemy. In his opinion the principle which should be adopted was that suggested by the London Traffic Commission, which consisted of an extraordinarily able body of men of various political opinions. That Commission unanimously recommended the formation of a Traffic Board, which, however, the Progressive party at Spring-gardens had blocked owing to their jealousy and obstinacy. The only way in which the present state of affairs would be remedied was by the appointment of a Traffic Board, which could look ahead for twenty years, consider the matter in all its bearings, and produce a practical solution for the troublesome problem of the locomotion of London.

Mr. Sidney Straker thought that if motor 'buses were to be allowed to be used as a section of the vehicles in London for public carriage purposes, the Central Traffic authority which at present existed would have to be overhauled. Owing to the heavy restrictions which now existed, unless some revision was undertaken it was obvious that not only would the using companies be a non-existent quantity but the manufacturers as well. At the present time they were in the same position as the Commissioner of Police, namely, between the devil and the deep sea. A car which would be passed by the authorities at the present time would not be passed a month hence, with the consequence that the makers were nonplussed and incapable of designing a vehicle which complied with the requirements of the public authority. At the present time a quarter of a million pounds worth of completed motor 'buses were awaiting licenses from the public authority in London, and it was a crying demand that a central authority of capable and competent men should be appointed. The way also in which the using companies were conducting their respective businesses was causing considerable anxiety in the minds of manufacturers. Beautiful machines, composed of materials which were unheard of before the days of automobile construction, were now being produced which worked from 16 to 18 hours a day continuously, ran 30,000 miles within 12 months, and earned substantial profits; but, unfortunately, the using companies tried to get all they could out of the machines; and this was inconsistent with sound practice. One spare car was required for every six or seven vehicles. If a motor garage was established and conducted on thoroughly sound lines, there would never be a car in it which would not perform its daily function of utility. But, unfortunately, the cars were put on the road and allowed to run themselves to death, the companies often not realising that an efficient inspection every seven or eight days would render the car, at a small expense, serviceable for another week without further outlay. It was difficult in a new industry to instil into the minds of the users the important features which controlled success, and that was a source of worry to the manufacturers. A good deal was heard of electric vehicles, but he thought it would be a long time before the existing motor omnibuses would be supplanted by such machines. At the present time motor omnibuses were running silently at a cost of from 8d. to 8½d. per car mile, including everything except depreciation, and such a cost should yield a substantial profit to the user. All that remained to be done was to put into proper shape, firstly, the authority which controlled the licensing; and, secondly, the using companies which controlled the employment of the vehicle.

Lord MONTAGU, in reply, thought he was to be congratulated on the practical unanimity which had been expressed on the main conclusions of his paper. He would have gone further into the subject of the Municipal aspect of tramways versus motor buses, but, as he stated in his paper, he did not wish to infringe upon a part which peculiarly belonged to the Chairman, or to enter into a subject which was political and controversial before a non-political audience. When recently analysing the cause of the noise on some of the London 'buses, he was very much surprised at the results. In one case he found that two cans near the driver's feet were jarring together; and on the same omnibus, which otherwise was perfectly noiseless, the advertisements, consisting of iron sheets along the top were loose and rattling, the screws being inadequate to retain them in their positions. Such things created unfavourable impressions; and he, therefore, recommended the proprietors and managers of motor omnibuses to see that the interesting advertisements which appeared on their vehicles were secured with strong bolts, or in such a way as to prevent their rattling. He felt quite certain all reasonable motor omnibus advocates would agree that in the future motor omnibus routes must be defined. When he was defending the cause of the motor omnibus in the House of Lords last July, he did not think any prejudice was displayed in the Upper House against it, in fact the reverse; but he thought the public was now making a reasonable demand that motor omnibuses, at any rate at night, should confine themselves to certain main routes. All those who had slept in a building adjoining a motor 'bus route at night would agree that that was a reasonable proposition. He desired to congratulate all those concerned on the increasing reliability of the motor omnibus. He remembered when a 'bus stranded at the side of the street was a common object, but breakdowns had now been considerably lessened, with a corresponding improvement to the industry. The problem of the motor 'bus was a great deal more than a purely mechanical one; it was a great coming force in the nation, for the welfare of the democracy in town and country alike. He believed that free, unfettered, cheap and safe locomotion was exactly analogous to the free circulation of blood in a human being. Just as blood, if it became congested in any part, produced dire results, so the congestion of humanity and their inability to travel easily produced equally bad social results. He was quite certain that the improvement in comfort, noiselessness, and cheapness of the motor 'buses would all tend, not only to make them a most valuable force for good in the towns, but also to the nation as a whole. In conclusion, he desired to refer to the death of M. Serpollet, the pioneer of steam-omnibus traction in France, who had done perhaps more than any other man in the early days of steam-motor public service vehicles for the advancement of the industry. His steam system, though it had its critics, was a very efficient one, and was adopted very widely. He was sure they all condoled with the family of the late M. Serpollet, and with the French scientific world, in the loss they had sustained.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Lord Montagu for his interesting and instructive paper, and the meeting terminated.

GOLD MINING IN KLONDIKE AND ALASKA.

According to recent reports from Dawson a gold dredging epoch is dawning upon the Klondike. The rich, early discovered creeks have already by crude and wasteful methods been worked over. They are now being subjected to another, and more scientific treatment. A prominent feature of the new system is gold dredging. It has proved eminently successful in the Klondike in spite of such drawbacks as difficulties of transportation, high cost of installation and working, frozen gravels and short seasons. Gold dredging in the north has passed the experimental stage, and become an established and prominent industry. Extensive areas of low grade ground which have been lying idle, because under the former manner of mining the cost of extraction would equal, if not exceed, the returns, are being made productive through the use of dredges handling 3,000 or more cubic yards of dirt every twenty-four hours. There are now in the Klondike, either in operation or in course of installation, nearly a dozen gold dredges, and these have been proved of great success. Even the old form of prospecting by shaft sinking has been largely superseded by the use of steam churn drills. The operations of the dredges in 1906 confirmed the results obtained by the pioneer dredges of 1905, viz., that the auriferous gravels in the Klondike which can be treated by dredging are so extensive that placer gold mining there is absolutely assured to be a vast and permanent industry. According to a report from Ottawa the great advantage of workting claims by dredges and efficient hydraulics has become so apparent that during the summer of 1906 the owners of many of the claims on the older creeks and hills preferred not to work their properties by the more primitive method, but to await the installation of dredges or a large supply of water. For this reason the number of gold-yielding claims has been temporarily greatly reduced. Notwithstanding this fact, however, the gold output up to October 31, 1906, amounted to £1,079,000. In 1905 the output for the whole year amounted to £1,500,000. It is stated in a report of the Commissioner of the Yukon territory that on the creeks situated north and west of the Indian River divide, namely Bonanza,

Eldorado, and Hunker creeks, with their tributaries, the primitive placer mining methods have almost entirely given way to modern methods, but on the Indian River side of the divide, owing to the expense of transportation, and the generally more virgin nature of the claims, primitive placer methods, aided by a few mechanical contrivances, are still employed. This section includes Dominion, Gold Run, Eureka, Sulphur, and Quartz creeks, and their tributaries. Another noticeable feature in the mining industry of the Klondike during 1906 was the great activity displayed by prospectors and claim locators. The extent of this can best be shown by comparing the number of claims staked during the two past years with those staked during the four months of July, August, September, and October, 1906. During the fiscal year ended June, 1905, there were 785 claims staked, and 505 during the fiscal year ended June, 1906. During the four months ended October, 31, 1906, there were 1,388 claims staked, that is to say, during the said four months there were more claims staked than during the whole of the two preceding years. While in the north end of the territory placer mining has received nearly the entire attention of miners, in the south end, in the vicinity of Whitehorse and Conrad City, quartz mining has been the principal industry. In the immediate vicinity of Conrad City about £120,000 has been spent in developing the quartz properties. The "Venus," "Vault," "Montana," and "Big Thing" mines have been energetically and systemataiclly developed. Reverting to the question of gold dredges, those so far employed are, according to the United States Consul at Dawson, of American make. Occasionally, it is said that dredges from other countries may enter into competition with American patterns. As a matter of fact, machinery and appliances of a kind not made in Canada, for use exclusively in alluvial gold mining, are admitted free of duty in Canada. Under this provision most of the component parts of a modern gold dredge may enter Yukon territory without paying customs duty. Having passed through the first and primitive stage of gold mining (washing out gold by the use of pans, rockers, cradles, sluices, &c.), the Klondike is now entering upon the second stage of placer mining development, employing hydraulic and dredging machinery. Later on will probably follow the third and still more permanent method of gaining the golden metal, that is, quartz mining. It is expected that the introduction of dredges will greatly increase the output of gold in the Klondike. In 1905 this was reduced to about £1,500,000, as against £2,100,000 in 1904, £3,600,000 in 1901, and £4,450,000 in 1900. Speculation is already rife as to whether this enlarged supply from the Yukon, coupled with Alaska's growing yield of new gold, will not perceptibly affect the general economic conditions in America as a whole. During 1906, it was estimated that Alaska furnished some £4,000,000 of gold, as against £2,900,000 in 1905, £1,800,000 in 1904, and £1,300,000 in 1903. The increase in 1905 in Alaska of gold production was due largely to the opening and working of the Tanana and some minor districts. The output of the Tanana country in 1905 was valued at £980,000. The Nome district remains a large producer, having turned out £920,000 during the year. The receipts of gold bullion at the United States Assay Office at Seattle during 1905 included —From Nome, 225,565 fine ounces; Tanana, 235,324; other Alaska regions, 46,319, and Yukon Territory, 416,432 fine ounces. The Douglas Island mines continue to supply the whole output of lode gold.

IMMIGRATION INTO THE UNITED STATES.

The Hon. R. C. Lindsay, who is the Second Secretary to His Majesty's Embassy at Washington, has written an interestsng report on immigration into the United States, issued as a Foreign-office paper (Cd. 2683). Between 1820, when the United States Bureau of Immigration originated, and 1905, no less than 25,900,000 immigrants reached American shores, and in no year was the immigration so great as in 1905, when it amounted to 1,026,000. The first great impulse was given by the commercial depression in England in 1827 and 1828, and was carried on by hard times in Ireland till 1842, when the 100,000 was first passed, and till 1847, when 234,000 entered. The revolutions on the Continent brought immigration up to 427,000 in 1854, after which it fell, till during the civil war, in 1862, a bare 100,000 entered. After rising to 459,000 in 1873, commercial depression in the United States brought it down again in 1878 to 138,000. In 1882, partly on account of the "May laws" in Prussia, 788,000 immigrants reached America. Diminution then set in, and the commercial depression brought about a low point in 1868 of 229,000, since when the increase has been uninterrupted, and the figures of the present year exceed even those of 1905.

The explanation of the rapid increase in immigration during the last decade is not far to seek. Increased facilities of transit are the first and most obvious cause. The journey is not the great and difficult undertaking it used to be. Fares are cheaper, accommodation better, and sailings regular. Many peasants in Eastern and Central Europe have been induced to sell their plots of land and immigrate by the dreams of easily acquired wealth which touts and runners bring up before them. Mr. Lindsay says that immigrants have been seen to throw their cooking pots into the sea when their vessel enters an American harbour, in the belief that when once ashore new ones were to be had for the asking. Another cause of immigration is the Protective Tariff. By developing certain kinds of industries, and shutting out foreign goods, it creates a demand for certain kinds of labour, and destroys a demand for foreign goods. Obviously,

if the goods are wanted, and may not be imported, producers of them must come in.

Not only has immigration to the United States increased very largely during the last two decades, its character has changed. Up to 1880 it was the people of Northern and Western Europe who contributed the vast majority of foreign population to America, Englishmen, Irishmen, Germans, and Scandinavians, but now the majority comes from Southern and Eastern Europe and is chiefly Latin and Slavonic. This is shown very plainly in the following Table :—

	Nationality.	Average Annual Immigration, 1880-85.	Rate of Illiteracy.	Average Annual Immigration, 1900-05.
		No.	Per Cent.	No.
N. and W. Europe (chiefly Teutonic and Celtic) ...	German	174,109	8	32,583
	Scandinavian	69,665	0·6	53,798
	British	145,708	3	72,248
S. and E. Europe (chiefly Latin and Slavonic) ...	Russian	14 290	26	124,920
	Austro-Hungarian	27.642	26	176,574
	Italian	20.309	48	176,650

It is estimated that 46 per cent. of the present population of the United States is due to immigration which has taken place since Colonial times, but whereas in the past the emigrants were men of northern blood, now nearly three-fourths of them come from Southern and Eastern Europe, with the result that an immense number are illiterates. Of the total number of immigrants in 1905, 725,000 were males, and 300,000 females. 114,000 were under fourteen years of age, 855,000 from fourteen to forty-four years old inclusive, and 56,000 above that age. 238,000 were illiterate, and the total money shown by them on landing was 25,159,012 dollars, or an average of nearly 25 dollars per head. It is a little surprising that whilst the percentage of English immigrants who are illiterate was only 1·8, of Scotch 0·5, and of Irish 2·9, the percentage of German was 3·6. The most illiterate of all are the Ruthenians, the percentage being 59·7, the Lithuanians coming next with a percentage of 52·3, followed close by Southern Italians with a percentage of 51·2. Poverty and ignorance seem to go together, the most illiterate having the least money in their pockets. Thus the Lithuanians average 12·1 dollars, and the Ruthenians 12·04 dollars, whereas the Germans take with them an average of 43·7 dollars, the English 57·40 dollars, and the Scottish 50·06 dollars.

As with other races, the States of New York, Pennsylvania, Massachusetts, and Illinois gain the largest number of British immigrants, but on the whole, Englishmen are better distributed throughout the country than people of other races, and surprisingly large numbers of them are to be found in the far Western States. Of the wage earners, 33 per cent. are professional men or skilled workmen. Englishmen assimilate quickly and easily. The Irish differ in one respect from all other races, in that their female immigrants outnumber the males—29,000 to 24,000 in 1905. Most of the women, like the Scandinavians, are domestic servants of whom Ireland contributes no less than 23,000—last year one-fifth of the total number of servants who arrived. Of the men, about 16,000 are unskilled labourers, but the Irishman is being ousted by cheaper races. The German immigration is one of the oldest and most considerable, and stands second only to that of the United Kingdom. A large proportion of the German immigrants, though not so large as in the case of the British, are engaged in professional and skilled occupations — clerks and carpenters being the most important classes. They are well distributed, but have also concentrated in certain well-defined centres. In New York the German has supplanted the Irish vote in first importance. Chicago contains 170,000 of them, and 60 per cent. of the population in Milwaukee are of this race. They have taken the lead in establishing many industries in the United States, notably that of brewing. They make excellent immigrants, as do the Swedes, Norwegians, and Danes. "Better even than a Norwegian" is a phrase that may be heard sometimes as the highest praise possible for a servant or workman, and it is not easy to know which of the three races is rated highest.

For some time the Italians have formed the largest group of immigrants, but it is thought this immigration has reached its highest point, and the numbers for 1905, high as they were (221,479) did not come up to those of 1903, when 233,000 arrived. Like other races, most of the Italians go to New York (which claimed 90,000 in 1905), Pennsylvania, and Illinois, with large contingents from Massachusetts and Cincinnati. 45,000 Northern Italians found their way to California, where they are mostly engaged in fruit farming, and are doing well. The padrone system is a characteristic feature of Italian immigration. The padrone contracts with the runner or tout in Italy to receive a certain number of able-bodied men, and on arrival he immediately hires them out to work. The disadvantage of the system is that the labourer is mulcted of a small per-centage of his wages as commission, which in his poverty he can ill afford, and that in many cases he must buy his food from the padrone at more or less exorbitant prices. The Italians do not assimilate easily. They congregate in large colonies, and learn English slowly and badly. They are cheerful and improvident, and from the very lowness of their standard of living, they keep fairly clear of pauperism. The average weekly cost of living in a family for an Italian has been worked out to be no more than 82 cents.

The Jewish immigration to the United States is large. Hebrew immigrants almost without exception find their way to the large cities. New York has a

Jewish community of 600,000 souls, and in 1905 received 83,000 more out of a total immigration of 129 000. The remainder go mostly to Pennsylvania, Massachussetts, and Illinois. The Jews are of poor physique, and incapable of heavy and manual labour. They are, therefore, compelled to follow City callings, and, in spite of illiteracy, more than half of the 1905 immigrants were skilled labourers, and no less than 22,000 declared themselves to be tailors. 8,000 were servants, and only 12,000 labourers. Mr. Lindsay says that the Hebrew immigrant does not make so bad a citizen as is usually expected of him. His law-breaking is confined for the most part to some breach in the sanitary regulations committed in the interest of thrift. He is sober, industrious, and shrewd, and intense pride of race generally saves him from falling into the last strata of society. But he is liable to disease, especially tuberculosis, and it is to be feared that his physical degeneration is often accompanied by a deplorable moral degradation, which alone can account for the number of wife desertions in the community. In 1905 the United Hebrew Churches in New York attended to a total number of 10,066 applications for relief, representing 44,000 persons. Of these no less than 1,100 were deserted women, who had 2,890 children.

The Syrians and Armenians seem to be the most undesirable of the immigrants reaching the United States. They form little colonies, and live in a horrid state of dirt and congestion. The first thing they do is to commit their children to the poor-house, and it is said that there are not 100 Syrian children in all the public schools in New York. Their presence in America shows that even the most stringent laws cannot keep out a bad class of immigrant.

The first General Immigration Act was passed in 1882, but nearly every Congress has had the matter under consideration since that date, and in proportion as the flood has risen, the stringency of the laws has been increased by adding to the "excluded" classes, by improving the administrative machinery, and by putting more responsibility on the shipping companies. Though the present law is the outcome of the experience of twenty-five years, there is a general demand for more stringent enactments. The New York Commissioner wrote recently, "I believe that 200,000 and probably more aliens came here last year, who although they may be able to earn a living, yet are not wanted; will be of no benefit to the country, and will, on the contrary, be a detriment, because their presence will tend to lower our standard; and if these 200,000 could have been induced to stay at home, nobody, not even those clamouring for more labour, would have missed them. Their coming has been of benefit chiefly, if not only, to the transportation companies who brought them here." Mr. Lindsay points out that it would be advantageous if a better distribution of emigrants could be brought about. The South is becoming an industrial country, and is dependent for labour mainly on the negro. Employers are almost unanimously agreed as to the extraordinary and increasing efficiency of the coloured labourer, but there is room for much more labour than he can supply. Yet last year the South received only 4 per cent. of the total number of immigrants. Societies for the assistance of emigrants have made endeavours to induce their *protégés* to go to new districts and found new colonies, but with poor success, and until some powerful organisation is set on foot with this object, it is unlikely much progress will be made.

COTTON CULTIVATION IN THE CONGO.

The results of the cultivation of cotton in the Congo Free State in which the Belgian Government has for some time been actively engaged, are now attracting considerable attention. The industry not only includes native cotton, which is found in different parts of the Free State, but also the introduction and cultivation of foreign cotton. Experiments have been made with the best known varieties, such as those of New Orleans, Georgia, Sea Island, Peru, and upper and lower Egypt. The first trials were made to ascertain the peculiarities of each species, the best time to plant, the particular care required for the culture and harvesting of cotton, and also to determine the varieties best adopted to the soil and climate with regard to quality and larger yield. The results of such experiments are being reported to the Congo cotton planters. According to a recent report from Antwerp, the Free State Government has brought out cotton pickers and presses of different patterns for the preparation and baling of the cotton for exportation. It has furthermore engaged the services of a practical American cotton planter, with a view to placing under his direction the management of its vast plantations. The first crop of cotton, in the year 1904, came from experimental plantations in the lower Congo. Samples were submitted to experts who found the quality excellent. Among the varieties produced, the Egyptian, grown in the district of Kalamu in the month of May, was quoted at the highest price, namely, one shilling per pound, other varieties such as that of New Orleans, cultivated under the same conditions, were quoted at a much lower rate. A sample of native cotton from Maiumbe, harvested without any particular care by the natives, was quoted at about seven pence per pound. This product resembles the Indian cotton which is used for coarse manufactures. In the upper Congo, plantations have been laid out, especially in the upper Ituri district, where the climate and soil seem to be particularly favourable to the cotton plant. Contrary to the conditions in other countries, the wooded districts there are not favourable to the cultivation of cotton. The moist atmosphere and the constant rains, which prevail in that part of the Free State territory, are most unfavourable, not so much to the growth of the cotton plant as to its maturing,

harvesting, and shipment. The Botanical Garden at Eala, situated in the equatorial district, is chiefly devoted to the gathering, selection, and distribution of cotton seeds. This establishment is already in a position to supply all demands made for seeds, but nevertheless the Government continues to import the seeds of the best known varieties. Not long ago the attention of the Governor of the Free State was drawn to the fact that the native chiefs would derive great advantages from the cultivation of the cotton plant, inasmuch as it has become acclimatised in all the regions, especially in the lower Congo, and the natives there are now familiar with its culture.

SUGAR-CANE PEST.

According to the American Consul at Trinidad, the sugar-canes in that island have been attacked by a small insect of the group, known as "spittle insects" or "frog hoppers." The name, "spittle insect," is given on account of the peculiarity of the immature insect in covering itself in a mass of white froth, which is voided from the tips of the abdomen, and which forms a complete hiding-place or covering for the insect within. The name, "frog hoppers," is probably derived from the name of frog spittle formerly given to the frothy mass, and from the leaping habit of the insect. Specimens of the infested cane stumps, and of the adult insect, have been sent to the Agricultural Department, and the following account is based on an examination of these specimens. The insect, when it has attained full growth, is about five-sixteenths of an inch in length, and about half as wide. The head and thorax are dark green. The wing covers, light brown, with two narrow whitish bands running across them. The head is stout and broad, the eyes prominent, and there are two small simple eyes on the upper surface of the head, between the large compound eyes. The antennæ are short and hair-like, except the base, which is much thickened. The legs are dark brown and slender, the wing covers are somewhat thickened, while the underwings are pale, tinged with smoky brown. The immature specimens, so far examined, are all in the last larval stage of development. The bodies are whitish, tinged with pink or red, the head and thorax being darker. The developing wings are seen as dark, elongated pods, lying on the basal part of the abdomen. The adults have not been observed in the act of feeding. The immature insects seem always to place themselves on young tender roots, and it is probable that they are able to penetrate the hard rind of the cane with their beaks. They have been found feeding at a distance of four inches below the surface of the soil. The chief of the Trinidad Botanical Gardens, states that this insect appeared on the island a few years ago, during such a season of constant wet weather as the last, and the fact that it has remained comparatively unknown since that time, would indicate that it becomes a pest only is seasons unfavourable to the cane.

ARTS AND CRAFTS.

Wood-carving.—We are all quite well accustomed to old works of art being bought for America. If we hear that a well-known picture has come into the market, or that a collection of any importance is to be sold, we immediately begin to speculate on the likelihood of its finding its way across the Atlantic. It is not quite so usual an occurrence for an American to buy the work of a modern European artist, and still less common for him to place orders in the hands of an English craftsman. He is rather inclined to think that, when it comes to work which is being executed to-day, he can do as well at home as he can elsewhere—if not better. It is, therefore, with a certain feeling of surprise, not unmixed with pleasure, that we learn that the masterpiece of technique in the way of modern wood-carving on view at Mr. Aumonier's studio is destined for New York. Wood-carving is not a craft about which, in the ordinary way, there is very much to say. It has long passed the experimental stage, and no one expects any startling new developments; the nature of the work is fixed within certain fairly rigid boundaries by the limitations of the material and the tools employed. Still, in the most technically perfect of crafts, as well as in the most elementary, there are, from time to time, signs of movement—points of departure from the beaten track—which, though they do not indeed introduce a new technique, or pave the way for violent revolutions or reformations, are at least worth noting as steps forward along the path of craftsmanship. It is just one of these steps forward that seems to have been taken in the piece of work which has just been finished in Mr. Aumonier's workshop. The carving is part of an overmantel for an elaborately appointed room, in a style which implies ornament of a somewhat florid character. It takes the familiar form of a central cartouche, a couple of big, fat swags, and some dependent bunches of flowers, connected by ribbon work and bows of exceptionally graceful design. The carving, which is ultimately to be very lightly gilded with powdered gold—rubbed off in places so as to show the red colour of the composition grinning through—and mounted on a green background, is executed in limewood. The ribbons, naturally in rather lower relief than the rest of the work, are carved out of the solid wood, whilst the projecting parts of the more prominent bunches of ornament which rise to a depth of at least six inches in places, are cunningly planted on. The work is remarkable not only for the height of the relief and the skill of the carving, but for the taste which has induced the carver, in spite of the rather florid style of the design, to treat his work with restraint and breadth. There is nowhere any frittering away of the surface of the wood. Of course, limewood would not keep its colour for long, nor would it turn to a pleasant

tint in its old age, and it would have been impossible to execute this very intricate and deep kind of carving in a less tractable wood; but it seems almost a pity, from one point of view, that a surface which bears such evident traces of skilful workmanship should have to be covered up by a coat of preparation and gilding, no matter how slight. From another standpoint, of course, the effect of the work as a mass may quite possibly be improved by its translation into green and gold.

Stone-carving.—Stone-carving and wood-carving are so closely allied both in theory and in practice, that it is interesting to compare with the piece of work just noticed, the carvings which form part of the exterior decoration of the new building for the United University Club, at the corner of Pall-mall East and Suffolk-street. The comparison is the easier, because in both cases the theme of the ornament is the same, and in spite of the great difference of treatment there is a certain resemblance between the two pieces of work. The ornamental details of the new club have been carved from designs by Mr. Reginald Blomfield, and are thoroughly different in feeling from those in the wood-carving, but in spite of that, and allowing for the limit naturally imposed by the stone upon the craftsman, there is a certain family likeness between the two. The admirable reticence of the design of these stone garlands makes them thoroughly fitted for the place they occupy on the building—whilst the two figures supporting the shield over the main entrance, the work of Mr. Pegram, are in character with the rest of the ornament and with the general style of the building. It is not often that we have so good a chance of seeing at the same time the work of one carver in two materials showing so well the points of likeness and of difference which follow inevitably and naturally from working in different and, in some respects, dissimilar, media—which yet are handled in more or less the same way. It is also interesting to note how well this massive and sparingly-used stone-carving goes with the building it decorates, and how it seems to form an almost necessary part of the building instead of calling undue attention to itself or taking up space which would have been better left free from ornament.

Embroidery.—It is some years now since the public had an opportunity of seeing a really representative collection of modern English embroidery. And it can hardly be said that the exhibition which has just been held at the Grafton Gallery by the Royal School of Art Needlework does more than show the lines upon which one school has been working of late. The school made its name originally by "crewel work," and the authorities are probably wise in keeping this kind of embroidery well to the front in the exhibits—more especially since, at the present time, crewel work in imitation of that done two or three centuries ago is in high favour. One of the most satisfactory pieces of work on show was the valance and set of curtains of medlar trees—designed as well as executed at the school. In this work, as in much of the old embroidery, the back-ground, a kind of bolton sheeting, is left bare and the pattern stands out in many-coloured crewels. The general effect is pleasingly reminiscent of the old work without being in any sense a copy of it—indeed, the design, though by no means what is called "up-to-date," is nothing if not modern in its composition. In the large hangings, executed entirely in crewel embroidery, in which no fraction of the original ground material remains uncovered, the result does not seem proportionate to the labour spent on them, though they are not without interest. These panels are neither more nor less than huge pictures in embroidery. There is a good deal of divergence of opinion on the question of picture-painting in embroidery. Some people hold that what it is possible for the needle to do may well be attempted in needlework. Others are firmly convinced that pictorial effect is out of place in embroidery and that if anything more than ornament is attempted in it, it should be treated so that the final effect is first and foremost needlework—something which could hardly be arrived at by any other method of workmanship—and not a more or less imperfect rendering in silk or crewel of something which could be more perfectly executed with the brush. Whatever we may think on that point, there is no doubt that, for the time being, picture painting in embroidery has come back into prominence. The little show of Miss Button's wonderful and really charming landscapes in embroidery held last year at the Lyceum Club gave striking proof of what it was possible to achieve in this way. The pictures were wonderfully well drawn and very clever use was made in them both of the stitches and the colours employed. But the desire for picture has not stopped short at work like this, and there is a quantity of needlework now being done which does not keep so strictly to the rules of the game. That is very largely because it aims at pictorial effects not to be got by the needle—an aim which stands confessed by the practice which has become customary of painting the smaller and more minute parts of the design (the flesh and various other details) in water colour. This, by the way, is a proceeding which carries us back with unpleasing insistence to a debased period of art. It recalls also a practice of the modern Belgian trade embroiderers whose work, mechanically good as it sometimes is, is by no means artistic. The difference between this kind of thing and the cheap fancy work in which a stencilled filling is outlined and added to by silk embroidery is great indeed, but the commoner work represents only the very thickest end of the self-same wedge.

OBITUARY.

ERNEST GEARING. — Mr. Gearing, managing director of the Leeds Forge Company, died on the 8th inst., in London, after a severe operation, at the age of 57. His early training was obtained at the chief engineer's office of the Union Steamship Company at Southampton. He left the south of England to become the works manager of the shipyard of Messrs. James and George Thomson, Clydebank, Glasgow (now Messrs. John Brown and Co.) and superintended the building of the steamships *City of Paris* and *City of New York*. In 1892 he became general manager and secretary of the Leeds Forge Company, and for the past two years was managing director of the company. Mr. Gearing was elected a member of the Society of Arts in 1896.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock :—

FEBRUARY 20.—"The Commercial Application of Refrigeration." By HAL WILLIAMS. SIR EDWARD MONTAGUE NELSON, K.C.M.G., will preside.

FEBRUARY 27. — "Modern Typewriters and Accessories." By ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts.

MARCH 6.—"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S. The Right Hon. LORD HARRIS, G.C.S.I., G.C.I.E., will preside.

MARCH 13.—"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc.

Dates to be hereafter announced :—

"Smoke Prevention in Factories." By JOHN B. C. KERSHAW, F.I.C.

"The Underground Water Supply of the Thames Basin." By CLAYTON BEADLE.

"Engraving and Photogravure." By. J. CRAIG ANNAN.

"Hungarian Arts, Home Home Industries and Commerce." By LOUIS FELBERMAN.

"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon.

"Aerial Navigation." By MAJOR B. F. S. BADEN-POWELL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras. The LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States. SIR FRANK SWETTENHAM, K.C.M.G., will preside.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

MARCH 19. —"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. This paper has been unavoidably postponed from February 19th.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

LECTURE I.—FEB. 25.—What Romanesque is—French examples—Oriental features—The portals at Chartres—Provençal developments—Direct Oriental influence in France and Italy—Norman Romanesque —Tau croziers — Fonts imported from Tournai—Sicilian Romanesque — The zig-zag—Scandinavian patterns—Spanish churches of 9th and 10th centuries.

LECTURE II.—MARCH 4.—Italian examples of Romanesqe ornament—Byzantine art and its formation—Patterns suggested by textiles—Arab influence —Byzantine influence in Italy mixed with Lombard —Subjects from the Arthurian Epic—Use of Byzantine ivories as models — Archaistic stucco work, affected by Byzantine ivories—Classical motifs copied —Decorative arcadings at Venice and Verona—Symbolical subjects.

LECTURE III.—MARCH 11.—Anglian carvings, — The Lindisfarne gospels — Italian workmen and

influence in Northumbria—Anglian ornament based on classical data — Later Comacines, called Lombards, and their activity—Italians in Germany and Byzantine influence on the Rhine—The goldsmiths of the Lower Rhine and the Meuse — Byzantine underlying forms and germs of 12th century patterns —English MSS. of the 10th and 11th century—Details which appear in later ornament—Reciprocal influence of England and Germany, and early influence of England upon France—English and Scots missionaries—The cloister the cradle of Romanesque — English and other ecclesiastical craftsmen, and work done by them—Summing up.

The lectures will be illustrated by lantern slides.

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 18...British Architects, 9, Conduit-street, W., 8 p.m. Sir Charles Nicholson and Mr. H. C. Corlette, "Modern Church Planning."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Professor J. Logan Lobley, "The Spread of the European Fauna."

TUESDAY, FEB. 19...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Colonel R. E. B. Crompton's paper, "Modern Motor Vehicles."

Statistical, 5, Adelphi terrace, Strand, W.C., 5 p.m. Mr. G. Udney Yule, "Statistics of Production and the Census of Production Act (1906)."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. Mr. John B. C. Kershaw, "The Present Position and Future Prospects of the Electrolytic Alkali and Bleach Industry."

WEDNESDAY, FEB. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Hal Williams, "The Commercial Application of Refrigeration."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. Edward Mawley, "Report on the Phenological Observations for 1906." 2. Mr. Richard Inwards, "The Metric System in Meteorology."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. J. W. Gordon, "An Early Criticism of the Abbe Theory." 2. Mr. James Murray, "Some Tardigrada of the Sikkim Himalaya." 3. Dr. Eugène Penard, "Some Rhizopods from the Sikkim Himalaya."

United Service Institution, Whitehall, S.W., 3 p.m. Sir George Arthur, "Education in Relation to the Army."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, FEB. 21...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. The Percy Sladen Trust Expedition to the Indian Ocean. 1. Mr. J. Stanley Gardiner. Introduction. (Part I.) "Ceylon to Mauritius." 2. Mr. R. C. Punnett, "Land Nemerteans, with a Note on the Distribution of the Group." 3. Mr. L. A. Borradaile, "Land Caustaceans." 4. W. P. Cameron, "Hymenoptera." 5. W. F. F. Laidlaw, "Dragon Flies." 6. Professor A. Torel, "Fourmis des Seychelles, Admirantes, Farquhar et Chayos." 7. Professor G. H. Carpenter, "Pycnogonida."

Chemical, Burlington-house, W., 8½ p.m. 1 Mr. W. B. Tuck, "The Constitution of Oxyazo Compounds." 2. Messrs. T. S. Patterson and A. McMillan, "The Influence of Solvents on the Rotation of Optically active Compounds. Part IX. A New General Method for Studying Intramolecular-change." 3. Messrs. J. C. Irvine and A. M. Moodie, "The Reduction Products of Ortho- and Para-Dimethoxybenzoin." 4. Mr. G. Senter, "Replacement of Halogens by Hydroxyl. I. The Hydrolytic Decomposition of Hydrogen and Sodium Monochloroacetates by Water and by Alkali, and the Influence of Neutral Salts on the Reaction Velocities." 5. Messrs. A. D. Hall and C. T. Gimingham, "The Reaction of Ammonium Salts with the Constituents of the Soil."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. Alfred Harker, "The Minute Structure of Ignious Rocks and their Significance." (Lecture II.)

Optical, 20, Hanover-square, W., 8 p.m. Dr. W. Ettles, "The Ophthalmometer."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Professor J. J. Thomson, "Modern Theory of Conduction of Electricity in Metals."

Historical, Field-court, Gray's-inn, W.C., 5 p.m. Annual Meeting.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, FEB. 22...Royal Institution, Albemarle-street, W., 9 p.m. Mr. Dugald Clerk, "Flame in Gas and Petrol Motors."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. F. E. Walker, "Impurities in Boiler Feed-Water: their Nature, Effect and Elimination."

Botanic, Inner Circle, Regent's-park, N.W., 4 p.m.

East India Association, Caxton-hall, Westminster Town-hall, S.W., 4 p.m. Mr. J. D. Anderson, "Constitutional Problems in India."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Physics Laboratory of the Royal College of Science, South Kensington, S.W., 5 p.m. Professor Lyle, "Transformer Indicator Diagrams." Professor Bragg, "Ionisation of Gases by α Particles of Radium." Mr. B. Roberts, "A Micromanometer."

SATURDAY, FEB. 23...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture II.)

NOTICE TO LIBRARIES.—The Secretary of the Society has in his possession a series of British Association Reports from 1878 to 1890 (13 volumes), and a series from 1872 to 1889, with the exception of 1881 (17 volumes). These he will be glad to present to any Library, or Institution, which would like to have them.

Journal of the Society of Arts.

No. 2,831. VOL. LV.

FRIDAY, FEBRUARY 22, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 25, 8 p.m. (Cantor Lecture.) F. HAMILTON JACKSON, "Romanesque Ornament." (Lecture I.)

WEDNESDAY, FEBRUARY 27, 8 p.m. (Ordinary Meeting.) ARTHUR E. MORTON, "Modern Typewriters and Accessories."

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

Wednesday, February 20th, 1907; Sir E. MONTAGUE NELSON, K.C.M.G., in the chair.

The following candidates were proposed for election as members of the Society:—

Aiyar, Narayana P. Hara, Local Fund Engineer, Anantapoor, Madras, India.
Alston, John, 88, Bishopsgate-street Within, E.C.
Clarke, His Honour Judge R. Johnson, 189, Broad-street, Monrovia, Liberia, West Africa.
Harward, Francis Vernon, 83, Dartmouth-road, Cricklewood, N.W.
Healey, Alfred E., 35, Marlborough-hill, N.W., and Constitutional Club, Northumberland-avenue, W.C.
Knowles, George Potter, Assoc.M.Inst.C.E., F.S.I., 39, Victoria-street, S.W.
Rutherford, Hon. A. C., Strathcona, Alberta, Canada.

The following candidates were balloted for and duly elected members of the Society:—

Clarke, Allen H., 74, Inverness-terrace, W.
King, Captain Alexander E., R.A., Ordnance Office, Citadel, Cairo, Egypt.
Mansell, Major John Herbert, R.A., 108, Shooters-hill-road, Blackheath, S.E.
Prevatt, Francis C., 106, Henry-street, Port of Spain, Trinidad, British West Indies.
Tanner, William Hugh, Public Works Department, Mombasa, British East Africa.
Weston, Robert Ogilvy, M.Inst.M.M.,A.M.I. Mech.E., The Globe and Phœnix Gold Mining Company, Limited, Que Que, Rhodesia, South Africa.
Yate, Colonel Charles Edward, C.S.I., C.M.G., 17, Prince of Wales's-terrace, W.

The paper read was—

THE COMMERCIAL APPLICATION OF REFRIGERATION.

By HAL WILLIAMS, M.Inst.M.E., &c.

The object of this paper is to bring to your notice the wonderful field which has developed for the application of refrigeration in the industrial world. Twenty-seven years ago mechanical refrigeration in a commercial sense was just beginning to feel its feet, and by means of the Bell Coleman Dry Air Machine, which produced its refrigerating effect by the compression, cooling, and expansion of air, perishable produce was first transported across the Atlantic. A few years later frozen mutton was being safely brought from New Zealand. An interesting account of the difficulties encountered by the pioneers in this trade was given to this Society by Sir Montague Nelson, our present Chairman, in a paper which he read some years ago.* The successful transport of frozen and chilled commodities by a natural sequence of events made it necessary for cold storage accommodation to be provided in this country for the reception of the produce which was being brought over. This method of trading in perishable produce opened such an enormous field for development that cold store after cold store, refrigerating depôt after refrigerating depôt, has been established, until now there are few towns in this country which cannot boast cold storage accommodation in some form or another, and there exists the Cold Storage

* See *Journal*, vol. xliii., p. 420.

and Ice Association which (*inter alia*) promotes and fosters the interests of the industry.

Mr. R. Maynard Leonard, the able editor of *Cold Storage*, has happily remarked upon the fact that the enormous trade in food products which has thus sprung up has an importance all its own, that is to say, it is becoming a political factor of the utmost consequence. Man cannot live by bread alone, and, as a writer in the *Engineer* pointed out some time ago, cold storage is "a phenomenon the international, political, and social importance of which is incalculably great."

It was also stated that "as food is the most fundamental material interest of mankind, this modern identical fact of cold storage is an irresistible political factor in enforcing the ever-increasing dependence for its natural welfare of each part of the world on all other parts." Mr. Leonard has deduced from these facts an overwhelming case against fiscal reform. In this, I regret that I am not at one with him, and, though I do not want to stray into a fiscal field, I should like to say that I have come to an exactly opposite conclusion. There is, however, another side of the picture about which there can be no question, and that is the extraordinary difference that cold storage of food has made in the health and comfort of the crews and passengers of liners and other steamships. It is doubtful whether, since the introduction of electric light, there has been any development of science which has proved such a boon to life on shipboard.

I do not propose to dwell for any length of time on the particular application of refrigeration to the supply of food, as the topic, from frequent use, is becoming somewhat hackneyed. I fully recognise also how extremely dull, to the majority of people, figures always are. It may be, however, that there are some members of the minority here to-night, and I am sure you will forgive me if for their sakes I point out that twenty years ago (1887), 1,500,000 sheep and lambs were imported from New Zealand, Australia, and South America, while last year (1906) from the same sources 8,800,000 were imported. One new refrigerated vessel alone could bring to London in a single voyage enough meat to give 1½ lbs. of beef or mutton to every man, woman, and child living within the bounds of the metropolis.

Refrigeration is also used for the manufacture of ice for domestic consumption. We in England have not yet cultivated what the Americans called the "ice water thirst," and I sometimes fancy, and always hope, that our damp climate will considerably militate against our ever doing so. Still, however readily the Western daughter may come East, the sun always advances towards the West, and it is difficult to know exactly what the future holds.

A great deal of the ice used in this country is imported from Norway; the balance is manufactured. Ice-making in this country, however, is to a very great extent a one-season business, and on those rare occasions when we do get a hot summer the ice factories are kept busily at work. In the winter, of course, their trade falls off. One of the best customers of the ice factories in nearly all cases is the "hokey-pokey" man with his decorated barrow of succulent, if germ-laden ice-cream. The germs, I may explain, are in the cream, not in the ice.

These are the two best known applications of refrigeration; there are, however, a whole host of other trade applications which are little known, and in many cases not even guessed at.

Refrigeration is applied by florists to the preservation of their choicest cut blooms, by nurserymen to the retardation of flowering shrubs and plants, such as lilacs, lilies, and other blooms for which there is a ready sale. It is also used by butchers, fishmongers, poulterers, brewers, chocolate manufacturers, dairymen, gelatine manufacturers, biscuit-makers, watchmakers, wine growers, iron smelters, hop merchants, horticulturists, and cheese makers.

It is used in the crystallisation of sugar and of salt; in the clarifying and concentration of wine; in the manufacture of explosives; in what are known as champagne factories; by candle-makers and oil merchants, by soap makers, stearine and paraffin wax refiners, by soda-water makers, margarine manufacturers; in bacon curing, in chemical manufactures, in cooling ammunition magazines on men-of-war, in the banana trade with the West Indies, in the manufacture of non-deposit beer, in shaft sinking, in mortuaries, and as a most valuable aid to pathological science. Another application upon which I will touch presently opens the field for the application of refrigeration to every trade in which it is necessary to remove moisture from the article manufactured or in process of manufacture.

It will perhaps be interesting briefly and generally to point out to you the way in which the application of refrigeration to all these in-

dustries varies, and to describe in a few words the peculiar uses to which it is put, why it is wanted, and the methods of application which are necessary to ensure the best results being obtained.

The use of refrigeration in hotels comprises the cooling of rooms for keeping meat, fruit, vegetables, and poultry, receptacles for keeping butter, milk and cream, coolers for containing wine and mineral waters, coolers for refrigerating water for drinking purposes, service refrigerators attached to every larder for keeping prepared food and made dishes in good order and condition before they are placed on the table, and a host of other minor applications which readily occur to the fertile minds of the chefs.

It is hardly possible to give refrigerating machinery a more difficult task than that of maintaining low temperatures in the cold rooms and expedition refrigerators in hotels. The kitchen staff is nearly always composed of Frenchmen, and the erratic, and often persistent, manner in which they leave the doors of the cold chambers open, leads one to believe that the laws of heat and cold in France must be different from those observed in other countries. If you add to this the fact that any article, from boiling soup to a live cray-fish, finds its way into the cold rooms, it will be obvious that the refrigerating capacity required has to be abnormally large to cope with the duty.

In spite of all these difficulties, however, a refrigerating installation has proved such a boon to all good chefs, that all hotels of any importance now have their cold chambers and their expedition refrigerators. In this connection it might be noted as a curious fact that all French chefs love ice, while, were it possible, Italians would, I believe, sleep in it ; at any rate they are better than any other nationality at handling it.

The enormous international trade which refrigeration has bred and fostered now makes it possible for a poulterer to stock his cold rooms with large quantities of foreign game which are brought over in a frozen condition, and to hold them until such time as the market is most favourable for their sale. In the same way fresh fish is kept on ice, while frozen fish is kept packed in boxes at a temperature of 16° Fahr. until it can be thawed out and sold. The frozen goods are taken from the cold room and placed in a room which is heated by electric radiators or similar means. This process of thawing, though useless for beef or mutton, is perfectly satisfactory for small articles, and the goods ready for sale are found to have suffered in no way from their long and chilly rest.

The success of the modern method of fishing by means of steam trawlers is almost entirely dependent upon a plentiful and cheap supply of ice, and the contents of the full hold of a trawler, if examined, will be found to consist of alternate layers of fish and ice. In this way the fish can be kept for a considerable length of time. In some trawlers, which were recently designed for a fishing company in New Zealand, a complete refrigerating and ice-making apparatus was fitted on board the boats, in order to manufacture ice for the purpose of keeping the fish during the length of the cruise, this step being rendered necessary owing to the fact that ice is not at present so easily obtainable in the coast-wise towns of New Zealand as it is in England. Several of our own trawlers now have cold chambers on board.

The bulk of the English fish supply undoubtedly comes from the North Sea, and every day Hull and Grimsby send enormous quantities of fish packed in ice by special trains all over the country. The waters of the South of Ireland, however, teem with fish, and there is no doubt that a little enterprise, aided by refrigeration, could profitably tap that source of supply for the English market. In this connection the newly-opened Fishguard route sounds propitious.

Amongst butchers the science of keeping and maturing meat for sale in large cities is of comparatively recent growth, and now all the best butchers have their cold stores, in which the meat is hung for days at a temperature of 35° Fahr. to mature. When matured it is removed for a day or two into a room having a temperature of 45°, in order that the temperature of the meat may gradually rise to such an extent that moisture from the atmosphere will not condense upon it, and spoil its appearance. It is extraordinary what a difference in flavour and edibility can be produced in apparently tough meat by maturing it in this way. Maturing meat has thus become the great secret of a high-class butcher's trade, and it is largely because the American and Argentine beef has matured and become tender on its voyage across the Atlantic that it is so delicious to eat and sells so readily. Mutton requires maturing in exactly the same way, and the butcher who desires to do a good business and earn a good name will never sell meat freshly killed.

The same rule applies to frozen mutton and frozen beef, but it must not be forgotten that these two articles when frozen remain for all practical purposes in *statu quo* until they are sent to market on this side. When they are thawed, they are, to all intents and purposes, fresh killed meat, and should be treated as such.

The essential feature in all chill rooms where unfrozen meat or articles of food are kept is ventilation. The ideal refrigerator for a butcher is an east wind. Absence of ventilation means a still and stuffy atmosphere, which in its turn means tainted meat.

There is no doubt also that a cool atmosphere is a great aid to prolonging the life of cut blooms, and in this way refrigeration comes to the aid of the florist. I recently designed some cooling chambers for a large West-end florist, and I am given to understand that in the summer great benefit is derived from keeping the cut blooms in a temperature of 45° during the night, and until they are wanted in the shop for sale.

It is, however, to the horticulturist that refrigeration has come as the greatest surprise and assistance. In the past, plant life has been retarded or advanced by the absence or presence of light and heat, and, by means of artificial heat, both fruit and flowers have been produced out of due season. This out-of-season production has, if possible, been brought to a greater state of perfection by the antithesis of this arrangement, or by the retardation of the development of life by placing the roots in a cold temperature. The principle is fairly obvious: all living things require a period of rest. In the vegetable kingdom, with a few exceptions, this rest is taken in the winter, while the work is done in the summer. In a cold store it is always winter, and so long as the life of the plant is not retarded to the point of extinction, its generation of new life can be kept back almost indefinitely.

With this knowledge, and the proper facilities for making use of it, at his disposal, the gardener of the day becomes practically master of the situation, and can make plants and flowers bloom or fruit just as and when he pleases. In fact, it is quite possible to-day to give an order to a horticulturist for a thousand lily of the valley blooms to be delivered at your residence on the 20th of June, July, or August next, or in fact any other date, and to pass the interval of time in perfect security that the order will be duly fulfilled.

There appears to be no reason why practically any root plant should not be capable of having its growth retarded by cold storage. Its use is at present confined to retarding varieties of bulbs, but any perennial should be, within limits, susceptible to the same treatment.

The method employed with lilies of the valley is as follows:—The roots are taken straight out of the cold store, and after they have been thawed in the ordinary atmosphere, are planted out under glass in beds or pots in the ordinary way. Lily of the valley crowns which have not been artificially retarded take six weeks in which to flower. Retarded roots are much more vigorous. The influence of warmth and dampness rapidly stimulates the dormant vitality. In a few days they begin to shoot, in a week the plants are growing strongly, and in less than a month they are in full bloom. It is a curious thing that the prolonged rest appears to have the effect of making the growth exceedingly rapid, once it is started.

It is an unfortunate thing that the climate in England is so changeable, for so long as the weather insists in reversing and mixing up the seasons as it does at present, it is necessary to keep a large selection of clothes of different degrees of warmth within easy reach, and it is consequently impossible for people to avail themseles to the fullest extent of the advantages offered by keeping their winter wardrobe in cold storage during the summer. Were it not for this, there is no doubt that a great benefit would be derived in several ways from sending one's stock of winter clothes and blankets into cold storage during the summer months when moths are most destructive. So fully has this become recognised, that a number of the largest furriers and woollen merchants have added cold stores to their establishments for the purpose of keeping the more valuable goods safe from the ravages of the moth. These cold storage rooms are kept at reduced temperatures, and are cooled by cold air circulation. The furs are kept hanging in bags which are suspended in the current of cold air. The blankets and woollen goods are folded and placed round the rooms on shelves. The furs which are stored for customers are taken in in the spring, when they are no longer required by their owners, and placed in the bags previously mentioned, which are sealed, and the seal remains unbroken until the owner comes to claim the goods. The principle is one which is likely to be considerably ex-

tended, and I have no doubt that in due course it will become quite an ordinary matter for households to send their out-of-season wearing apparel to cold stores to be kept safely for them.

If mechanical refrigeration has been a good friend to purveyors of perishable produce, it has also been a good friend to the brewer. In the process of brewing it is necessary to cool rapidly the wort, which is the liquid resulting from the mashing of malt and the boiling of the extract with hops after it comes from the coppers and before it is pitched with yeast for fermenting. It is also necessary to cool it and remove the heat of fermentation which is generated by the action of the yeast microbe. The heat to be removed during the former process is that which has been put into it during the process of manufacture; the heat to be removed during the latter process is caused by a more interesting state of affairs. During the conversion of barley into malt a substance is formed which is known as diastase. This converts the insoluble starch of the barley into a soluble and fermentable sugar, and this sugar, when absorbed as oxygen by the yeast, splits up into nearly equal proportions of CO_2 and alcohol. The true yeast microbe is a special form of cell whose normal condition of existence is one remove from the air, *i.e.*, anaerobic. It feeds on the nitrogenous matter present in the wort and breathes the combined oxygen of the sugar in the malt, splitting it up as described. The fermentable body, therefore, is the one capable of giving up its oxygen, and the ferment is the microbe having the power of taking it. Under the action of this microbe the excess of nitrogenous matter is absorbed, fermentability is decreased by the transformation of the sugar, and the beer is made staple by the addition in an active form of the alcohol which was previously present in the maltose in a passive one.

In addition to these two principal purposes, refrigeration is also used in breweries for keeping the beer cool while it is got into condition for sending out for bottling. In lager beer breweries refrigeration is essential. The lager beer itself is much less stable than the ordinary British ale on account of the comparatively small quantity of alcohol which it contains. In order to keep it in condition, therefore, it is necessary to maintain it at a low temperature, and for this reason lager beer is always kept and served in a cooled condition. Since grocers' licences were granted, and the Act which prohibited children from fetching beer from public houses except in a sealed vessel came into force, a great stimulus has been given to the sale of beer in a bottled condition. To get the best results from this beer, it is necessary to get rid of the deposit which always exists in beer, and which, as a matter of fact, is made up of the bodies of deceased yeast microbes. This is done by special treatment, and what is known as non-deposit beer is the result. The production of this non-deposit beer is effected by chilling, filtering, and carbonating the beer before bottling. The process of chilling is carried out by bringing the beer into intimate contact with brine artificially chilled by a refrigerating machine. The beer is then rapidly cooled from a temperature of 60° or thereabouts, to a temperature of 28° or 30°. It is then carbonated, filtered, and bottled. The lower the temperature of water or beer, the more CO_2 it is capable of absorbing. For this reason the beer previously referred to is reduced in temperature before carbonating. For this reason also soda water manufacturers are conscious of the advantages which the installation of refrigerating machinery gives them by reducing the temperature of the water before carbonating, thus producing a better quality of mineral water than is possible at ordinary temperatures.

It is a well-known fact amongst dairymaids and other people with agricultural instincts that the returns of butter from cream are to a large extent dependent on the temperature. Thus, if cream is reduced to a temperature of 48° Fahr. before churning, a much larger quantity and a much better quality of butter can be obtained from a given quantity than if it is churned at ordinary temperatures. At the same time, and in curious contradistinction, the cream will more readily separate from the milk at a temperature of 160° Fahr. than at any other. We thus have the peculiar phenomenon that, in order to separate the cream from the milk, high temperatures must be employed, while in order to separate the butter from the cream a low temperature must be used. Nature knows her own reasons best, but the superficial observer might perhaps be pardoned for thinking that in arranging matters in this way she gives an unnecessary amount of trouble. There is, however, method in her madness, because it is an undoubted fact that if milk is sterilised it is a less dangerous food than if it is not so treated. The bacteria which are so active, and which find so congenial a home in milk,

can be destroyed by sterilisation. Sterilisation can be attained at a temperature of 180° Fahr. This temperature, it is true, is not sufficiently high to afford absolute immunity from bacteria, but for all practical purposes it is sufficient, and there is no danger of burning. Thus we see the method, for though they have nothing to do with each other, the temperature which is desirable for sterilisation, which in itself is often very desirable, is also profitable for separation. It will probably be conceded by a student of human nature that nature was wise, and that many people who will not take the trouble to heat their milk to the sterilisation temperature for a good motive alone will do so when there is profit attached to it.

After pasturisation and separation, the milk is cooled down by refrigeration, and is returned to the farmers for calf feeding and other purposes. The cream is cooled rapidly in a similar manner, until it reaches a temperature of about 50°. At this temperature it is run into earthenware vats where it ripens for the churn. Practically it ferments, and owing to this lactic fermentation, the temperature rises to 70°, in the same manner as with wort in the brewery. In from 15 to 20 hours the cream is ripe and ready to be churned, but in order that the fat globules may not be broken and the butter become oily, and in order also, as we have seen, that the yield may be as large as possible, the cream is again cooled down to a temperature of 48°. In some 45 minutes the churning is complete, and the butter floats on the top of the whey in a fine firm condition.

In order to conduct this process, refrigeration is essential; in other respects it is a great advantage, in that it is highly desirable to chill the butter and cream before marketing it.

There is another use for refrigeration to be found in drying, and apart from the process benefits, by which is meant the advantages to the material being manufactured, of being able to dry at a low temperature, there is a second and more obvious benefit in drying by refrigeration rather than by heat—and that is, it is more economical. Except in very dry climates—and England has certainly not a dry climate—the atmosphere is saturated with vapour of water. The amount of this vapour which the atmosphere is capable of holding varies with the temperature, and this is why dew is deposited on the grass at night when the atmosphere is cold and is evaporated again in the morning when the air has been warmed by the sun. This evaporating principle has from the earliest ages been applied to drying, and when moisture has had to be removed rapidly from an article heat has been applied to it. By this heat the capacity of the surrounding air for absorbing water has been increased, and the moisture has been transferred from the article to the air. Were it practical continually to increase the temperature of this air it would be capable of taking up more and more moisture, but it is not practical, and therefore, when the air has become charged with moisture, it either ceases to do any drying or must be allowed to escape to make room for cold air, which in its turn is heated, saturated, and allowed to go to waste.

I do not know whether any of you have ever noticed that when you have a particularly obstinate problem confronting you a solution is often most easily reached by a complete reversal of all the elements involved. Thus, in drying by refrigerating, instead of continually heating air to a high temperature to raise its dew point, we lower its dew point and freeze the water out. Instead of admitting fresh air and letting the moisture-laden air go to waste, we use the same air over and over again.

Let us take a concrete example and explain how it is done. The goods to be dried are placed in an air-tight room: the air from this room is sucked by a fan and blown over a nest of coils which are kept at a low temperature by a refrigerating machine. In passing over these coils the air is reduced from a temperature of say 70° to a temperature of say 30°, or a 40° drop. At the low temperature it can no longer contain its moisture and this is deposited in the form of water or snow on the refrigerated coils. The air leaving the refrigerated coils at a temperature of 30° passes over some steam coils, which once more raise its temperature to 70°. It then passes back into the air-tight room, and when it comes in contact with the goods to be dried it is a perfectly dry air at a temperature of 60° and eager to absorb every drop of moisture it can. Owing to the outside air being at a temperature of, say, 60°, there is little or no loss of heat from the drying-room by radiation; therefore, all heat put into the air is usefully employed in drying the goods.

The duty to be done by the refrigerating machine consists in cooling so many cubic feet of air and in freezing out so many pounds of water; the duty to be done by the heating coil consists in heating the same quantity of

air to a temperature of 70°. The coal expended, therefore, does the work (*a*) of furnishing power to the refrigerating machine, and (*b*) of heating the air between the refrigerating coil and the drying chamber. It is a well recognised principle in refrigeration that a small number of thermal units expended in power can, under certain conditions, account for quite a large quantity of thermal units abstracted as heat; thus in freezing water a cooling effect of over 50,000 thermal units can be produced by the expenditure of 25,000 thermal units as power, and when the range of heat transference is less, as in the case of drying, this difference, or the ratio of heat extracted to work done, *i.e.*, the co-efficient of performance will be much greater and therefore the process much more economical.

It is frequently urged that where a large quantity of drying has to be done it is more economical to use steam engines for power and to dry with the heat of the exhaust steam than it is to adopt any other means of producing power or effecting drying. With exhaust steam the stock expression is "I get my heating done for nothing." If you don't think, the argument seems conclusive, but, if you do think it is really very erroneous, and a few minutes' consideration will show why. In order to make steam 1,000 B.Th.U. are required by every pound of water evaporated, a further 126 units are required per pound to raise that steam to a pressure of 100 lbs. per square inch; these 126 units or thereabouts are absorbed in the engine as work, the 1,000 remain in the exhaust. As no steam-engine can work with a closed exhaust pipe unless it is connected to a condenser, all exhaust heating coils have to have an open end through which a very large quantity of exhaust steam with all its heat escapes. If it were not allowed to escape freely the back pressure would be enormous, the engine would choke, and the power would be most inefficient.

For the sake of argument, take an engine of 100 horse-power, using 25 lbs. of steam per horse-power per hour at 100 lbs. pressure. The figures would be—heat in the steam 2,815,000 B.Th.U., of this 315,000 would be usefully employed in the engine as work, the balance, or 2,500,000, would be a waste product, some of which would be used for heating, but the greater portion of which must, owing to the exigencies of the case, be absolutely lost. It is very much a case of burning down the pig-sty to get roast pork.

Contrast this with the modern system. Power is produced by a gas-engine working with power gas. This is known to be quite four times as economical as the most efficient steam-engine. This gas-engine drives a refrigerating machine, which is really a heat pump and is most efficient when the range of temperature is small. This machine has to cool the air and extract the moisture—the lion's share of the work. The boiler has only to heat the cooled air, a much easier task. Further, it can heat it from a closed coil, where all the latent heat of the steam is made use of and none escapes as in the exhaust of an engine. We have already seen that at low temperature ranges, a refrigerating machine can remove heat in heat units far in excess of the heat in heat units taken as power to drive it; so that by the combination under review we effect the following economies:—First, superior economy of the gas-engine over the steam-engine; second, the superior economy of the refrigerating machine over the exhaust steam; and third, the superior economy of the closed heating coil over the open one. Add to this the superior manufacturing results obtained from drying at a low temperature, and the advantage of drying by refrigeration should be fairly obvious.

Drying by refrigeration has also been made use of on a very large scale for drying the moisture out of the air supplied to the blast furnaces employed in smelting iron ore. This application is a comparatively modern one, for though it has for many years been recognised by iron smelters that the blast furnaces are affected to a remarkable degree by the variations in the humidity of the atmosphere, the theoretical saving by the removal of this humidity has not been sufficient to justify any considerable outlay of capital. These theoretical considerations only take into account the heat which is absorbed in the furnace by the disassociation of the water vapour in the air blast and consequently only show a saving effected of about 4½ per cent. There are, however, very strong reasons to believe that the removal of the moisture from the blast has a very marked effect upon the oxidisation of the carbon in the coke, considerably increasing it, and consequently the evolution of heat per pound of coke handled.

In the years before 1904, Mr. James Gayley, of Pittsburg, gave considerable attention to this point, and so impressed did he become with the fact that the removal of the moisture from the air blast supplied to blast furnaces working under average efficiency

would effect large savings in coke consumption and increase the output of pig-iron, that he persuaded the Carnegie Steel Company to install an apparatus at its Isabella furnace at Etna, Pittsburg.

It must be remembered in considering this matter that the atmosphere frequently contains as much as 5 and 6 grains of water per cubic foot. From observations taken on the N.E. coast of England, the grains of moisture per cubic foot varied from a maximum of 5·14 in July to 2·83 in February, while in Cardiff the moisture was, as might have been expected, rather in excess of this.

One grain of water per cubit foot of air is equal to one gallon of water per hour per thousand cubic feet of air used per minute, or practically one gallon of water per hour. As a blast furnace of average size consumes about 40,000 cubic feet of air per minute, and as the atmosphere contains as much as 5 grains per cubit foot, the amount of moisture carried into the furnace would be equal to 200 gallons per hour.

As I have said, the theoretical loss produced by the evaporation of this water is not so very great, but, adding to this the practical gains obtained from the higher oxidisation of the carbon to which I have previously referred, the gains are very considerable, and, in fact, the economy observed by Mr. Gayley at Etna, resulting from a reduction of moisture contained in the blast from 5·60 grains per cubic foot to 1·75 grain per cubic foot, was an increase of pig-iron produced of about 25 per cent., and a reduction in coke consumed of about 20 per cent.

To instance a common illustration of the effect the moisture in the air has on heat and combustion, many of you will probably recall to mind the common saying: "It is freezing to-night, look how brightly the fire burns," this being only another way of stating that the atmosphere outside is dry.

To show how important the matter really is, and what enormous interests are involved, Messrs. Guest, Keen and Nettlefold decided only last year to spend many thousands of pounds on a refrigerating plant solely for the purpose of drying the air which was being blown into their blast furnaces.

I am afraid that if I continue to describe in detail the multitudinous applications of refrigeration you will grow extremely tired of the subject. I propose, therefore, to summarise more briefly those applications which I have not yet touched upon.

In chocolate factories refrigeration is of the utmost consequence, as, the melting point of chocolate being comparatively low, the process of manufacture cannot be carried out with any degree of certainty during the summer months. Further than this, our old enemy, moisture, again attacks us, for the sweets cannot be properly manufactured if the atmosphere is too moist. It is necessary, therefore, to provide means for cooling the chocolate down during the process of manufacture, and to dry the atmosphere of the rooms in which it is being made. The method of attaining these two ends must naturally vary with the circumstances of the case, and the quality of the chocolate manufactured; as the better class chocolates can always stand a higher temperature than the cheaper sweets. One of the difficulties presented in connection with applying refrigeration to factories where processes of this nature are being carried out is the fact that not only have the goods themselves to be cooled, but also the people employed in making them. In a refrigerating installation which I designed recently for a factory, the bulk of the work imposed upon the refrigerating machine consisted in removing the heat and moisture given off by over 100 girls who were working in the rooms, and in cooling the fresh air which they required to breathe.

The application of refrigeration to the manufacture of gelatine is somewhat similar, for it is required to enable the gelatine to set rapidly during the hot weather. Gelatine is, as many of you are aware, largely used in the manufacture of photographic plates and films. It is also used for the propagation of microbes and similar organisms in the lower scale of life. The indiscriminate propagation of these organisms, however, is not always desirable, and therefore it is necessary when manufacturing gelatine in bulk, to cool it down and make it set as rapidly as possible, in order to prevent the stray microbes from the atmosphere alighting upon it and setting up house.

When photographic films are being manufactured the atmosphere in the rooms has to be cooled, dried, and cleaned. For this purpose the air used in the room is, or should be, blown through water which is kept at a low temperature by refrigeration, and subsequently heated to the desired temperature. The act of blowing the air through the water not only cools it, but removes all particles of dust which would otherwise exercise a bad effect on the films and plates.

Refrigeration is utilised by watchmakers for the maintenance of an even temperature for the purpose of regulating and standardising their instruments; by hop merchants for preserving in the hops the essential oils which give them their peculiar aroma and flavour, and constitutes their value in the process of brewing; by cheesemakers in the storage and ripening of cheese, and it is in fact due to the systematic ripening of Canadian cheeses in cold storage before they are imported into this country that the market receives them so favourably, and is prepared to pay so high a price for them.

Attempts have been made in France for many years to try and concentrate the very light wines which are produced in such quantities, and contain such a low percentage of alcohol as to render them practically unfit for export purposes. These wines usually contain a great amount of albuminoids, which produce cloudiness in the wine when it is brought to a low temperature. The clarification of the wine is a simple matter, but the concentration has always presented considerable difficulties, for though a portion of the water could be frozen out, it was found that the water so frozen still retained considerable portions of the alcohol which it was desired to retain.

An Italian professor has, by a more or less secret process, overcome the difficulty, and has found that it is possible, by freezing the whole body of wine and filtering through it certain solutions, to concentrate it to the desired degree. The same process is now being applied to treating all sorts of sugary and syrupy solutions, and in the near future refrigeration will probably find a home in the sugar factories where concentration is now carried out by evaporation in vacuum pans and multiple effects.

In mining work refrigeration comes into play by enabling shafts to be sunk through water-bearing strata, or through running sand. The process employed is to drive a number of tube wells into the ground, in a circle surrounding the position in which it is desired to sink the shaft. Refrigerated brine is circulated through these tubes, and the soil surrounding them is gradually frozen. In due course the freezing extends from one well to another, and the result is a solid block of frozen ground. Mining operations can be carried out in this frozen ground with perfect safety, the soil being excavated and the sides of the shafts being lined with cast iron or similar material. By applying this method, a number of shafts have been sunk, more particularly on the Continent, through soil which had defied all other means of sinking, and valuable coal measures, which would otherwise have been lost, have been opened up for exploitation.

In the manufacture of candles refrigeration is employed for keeping the wax in hot weather at a temperature at which it will set. It is, however, most largely employed in the crystallisation of paraffin as it is extracted from the oil shales.

During the process of distilling these shales a number of oils of different specific gravities are obtained; the more volatile oils are recovered in the ordinary way, but those oils which become solid at ordinary temperatures, and when mixed with stearine are so extensively used for candle-making, have to be crystallised by means of refrigeration. The object is to separate efficiently the paraffin from the oil, and this can only be done by allowing the paraffin crystals to grow to such a size that the oil will drain away from them. Even then a large quantity of oil is, owing to its viscosity, held mixed up with the crystals, and filtration has to be employed to separate it.

The trade in fresh fruits from abroad has been revolutionised by refrigeration, as instance the banana traffic from the West Indies, the fruit trade from the Cape, and the apple trade from Australia, Canada, and the United States. The dried fruit merchant has derived considerable benefit from the application of refrigeration. Goods such as dried figs, raisins, nuts, &c., upon which there was at one time a heavy loss due to the activities of insect life, are now placed in cold storage as soon as they arrive in this country. This keeps them in good condition and prevents the insects getting at them. Cigar manufacturers benefit in the same manner.

I will not weary you by going further into the application of mechanical refrigeration, and, though details can be furnished on application, as the advertisements say, I think it will perhaps be best to pass over lightly the services which it renders in mortuaries and in laboratories. In any case, I think I have said enough to point out to you its extraordinary value to manufacturers, and the high place which it is taking amongst the processes embodying the application of applied science to the benefit of mankind.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said that until he heard the paper he had no idea that refrigeration could be applied to so many trades and processes. His only knowledge of the subject was connected with the meat trade, and he thought it would be of interest to the audience to know how important a part refrigeration played in the question of the food supply of the people. Although it had only been in existence for 25 years, refrigeration had been the means of supplying, in increasing quantities, cheap meat for the people of this country. For instance, in 1906 the amount of frozen and chilled meat imported was over 500,000 tons, 308,000 tons of which were mutton, lamb, and beef, 159,000 tons of chilled beef, and, most extraordinary of all, 40,000 tons of rabbits. In addition, there were imported, from the colonies only, 50,000 tons of butter and 100,000 tons of cheese. The industries connected with food were, he thought, probably the largest to which refrigeration could be applied, and certainly the most important to the people of this country, but from the many other trades mentioned by the author it was evident that it had a very wide field of application.

Mr. MATTHEW J. BROWN thought the author had presented in a vivid manner the extraordinary development of an industry whose growth was so recent that its beginnings were within the memory of most of those present. Until the various applications were brought together in Mr. Williams's paper, even one who was closely associated with the industry did not always grasp the wide application to which refrigeration could be applied. The author had shown, for instance, that it ranged from such a common thing as the penny ice-cream at one end of the scale, to the cooling of the blast used in great iron furnaces. Mr. Williams dated the beginning of the practical application of refrigeration to the introduction of the Bell-Coleman machine; and as he (the speaker) had the honour of being associated with Mr. Coleman when he was introducing that apparatus, he could look back with great interest to the time when the first cargo of frozen meat was brought across the tropics from Australia in the steamship *Strathleven* at the end of 1879 and the beginning of 1880. That was an epoch-making voyage, because from that small beginning had sprung the tremendous increase in the importation of food supplies to which the author had referred. He often thought that, if it had not been for the introduction of the refrigerating industry, the people in this country would be paying at the present day famine prices for their beef and mutton. He could not see how the country would have been able to raise the amount of meat necessary to give the population a good square meal.

Lieut.-Colonel CUNNINGHAM thought the chief interest of the paper lay in the fact that it drew the attention of the public to the vast field of the refrigerating industry, and the extraordinary variety of its applications. Although the industry was a new one, dating back only 25 years, probably the cause of its rapid development was that it had the effect of bringing into the country large quantities of cheap food. Its application to industries on a small scale were also of equal interest. One of its applications analogous to blasting was not mentioned in the paper. Blasting was ordinarily done with explosives, and one form of explosives was the violence of the action of expanding water. Water in freezing expanded slightly, bnt the small expansion was attended with great violence, and formed a very safe mode of producing an application of great force, whereby, for instance, stone could be broken up without the danger which arose when explosives were used. He desired to throw out one suggestion with regard to the application of refrigeration. Heat was applied in a practical way for the comfort of people by warming rooms by means of steam, hot water, and hot air pipes, but he did not know whether the cooling of rooms in hot weather had ever been tried on a practical scale. Attempts had been made in hot countries to produce this effect by placing blocks of ice round about the room, but while this had the effect of cooling the atmosphere in the vicinity of the ice it did not produce good results. He thought it might be possible to apply the circulation of brine or some cold material in pipes for the cooling of rooms. Although probably at first it would be an expensive process, it would certainly be productive of comfort, and he believed in time it would be cheap.

Mr. HENRY BRIER thought it would be of interest if he stated, in connection with the last speaker's remarks, that the rooms of a large hotel lately built in Bombay had been ventilated by means of cooled air being driven into them over brine pipes and with the aid of electric fans.

Lieut.-Colonel CUNNINGHAM stated that he was thinking of India principally when he made the suggestion. There was no doubt that it would be a great benefit to the British residents in India, in which country he lived for many years, if the rooms could be cooled in a moderately cheap and efficient manner. Twenty years ago, when he left the country, nothing of the kind was available, although passing the hot dry air of the hot wind through a screen of grass continually saturated with water produced an agreeable cooling effect.

Mr. R. M. LEONARD said that, although the author of the paper had referred to the commercial application of refrigeration in a wide sense, he did not

know that morgues and laboratories came under that category. One or two applications of refrigeration had been omitted from the paper; for instance, the large private establishment or mansion, in which gentlemen who kept up a large household found it paid them extremely well to keep a refrigerator for domestic purposes. Refrigeration had also had a great effect on the home markets, the retailer being able to buy his goods in times of glut and store them till the market rose. It had also been the means of raising the standard of living, and one of the great reasons why the industry had grown so rapidly was because it supplied large quantities of cheap food. He thought it would be found, if inquiries were made, that all industries which had developed so rapidly had been connected with some prime necessity of life. For instance, at the previous week's meeting of the Society Lord Montagu read a paper on motor 'buses, and as fast and cheap locomotion was an absolute necessity, the motor industry had naturally grown in a wonderful manner. The Chairman was probably in a better position than anybody to state how the refrigerating industry had added to the development of New Zealand and Australia, and it was undoubtedly the fact that nothing had so greatly aided the development of those colonies as the subject under discussion.

Mr. H. Carpmael said he had been struck with the marvellous ease with which refrigeration could be applied to a number of different things in the same building, it being only necessary to vary the temperature slightly to make it useful for various articles. For instance, wine could be kept at its proper temperature all the year round at the same time as fish or meat was being refrigerated, a fact which was amply exemplified in the hotels of the country. One application of refrigeration which was assuming considerable proportions, was the preparation of anti-toxin, which was prepared from a refrigerated solution of the dead bodies of the microbes to which Mr. Williams had referred. They were ground up by means of special machinery, and it was impossible to use the process unless the material was first frozen.

Mr. Arthur Williams said that the question of drying by refrigeration had interested him a good deal, and one of its applications which the author had not mentioned was that of efficiently thawing frozen meat. When frozen meat was taken out of a cold store and hung up in a butcher's shop, it had a large quantity of moisture deposited on it which spoilt its appearance; and a number of people had been endeavouring to devise means for thawing meat in such a way as to avoid the deposition of moisture. The ideal atmosphere which it was desired to attain was, he believed, that produced by a north-east wind, cold and dry. A number of processes had been brought out for that purpose, amongst them being an invention by the Chairman, which consisted in having a room fitted up with a series of freezing pipes set horizontally against the walls, and a series of steam pipes in the floor below a grating. That caused, without any mechanical appliance, a circulation of the air, the warm air rising off the steam pipes, and thawing the meat, afterwards depositing any moisture it had taken up, in the form of snow in the cold pipes, and continuing to circulate round and round. Meat was brought from the cold storage, where the temperature was from 20° to 25° F., and put into a room of such a temperature that no moisture would be deposited on it. That temperature was found to be somewhere about 45 degrees. The meat was kept for a certain time in that temperature, and then gradually raised to a temperature of 55 degrees, the highest practical point to which it could be taken. When the temperature reached 55 degrees, it was found there was a difference between the readings of the wet and dry bulb thermometers in the room of 10 per cent., showing a very considerable drying of the atmosphere. From start to finish, provided the temperature was properly regulated, there was no deposition of moisture on the meat. At the end of 48 hours, frozen mutton was found to be thoroughly and efficiently thawed, the same effect being produced in quarters of beef in four days. He believed those were approximately the times required to freeze the meat, so that the thawing appeared to be a reversal of the freezing method. Another application of the drying system of refrigeration mentioned by the author was that of drying photographic plates. In one factory with which he was connected it was found that one of the greatest troubles in drying in the ordinary way, by drawing in atmospheric air, filtering it through muslin, heating it up to 70 degrees, and passing it through the rooms, was the dust, which was not entirely eliminated by the muslin screen. To obviate that difficulty, a nest of refrigerated pipes were put in and a closed air circuit made. The author had said it was advisable to pass the air through a stream of cold water in order to eliminate the dust; but in working the refrigerated pipes he had mentioned, it was found that the moisture of the air was deposited on the pipes in the form of snow, and the dust appeared to be quite efficiently trapped in the snow, no trouble being experienced in the drying rooms from dust being deposited on the plates. Other applications of refrigeration could also be made in photographic plate factories. For instance, after the emulsion was made, it was put into small cooling chambers so as to cool rapidly and set; the plates were coated on a machine and passed over a slab which was cooled down by cold brine pipes, thus ensuring a quick setting of the emulsion on the plates.

Mr. Hal Williams, in reply, after thanking the speakers for the very kind remarks they had made, said that blasting by water which froze in the rock was very well known, in fact some of the alpine villages were more familiar with it than they cared

to be, because the freezing of water in crevices of rocks was the cause of a good many land slides and avalanches. The blasting effect produced continually frittered away the summits of mountains, and caused the constant falls of rock which took place. He was recently in an old chalk quarry the face of which he particularly remembered the last time he visited it was covered by vegetation, but he noticed that the whole of the face of the quarry was now perfectly white, large pieces of chalk having been blown off by the blasting effect of the ice. Mr. Brier referred to the Apollo Hotel, Apollo Bunda, Bombay, which was one of the most notable instances of the artificial reduction of the temperature of living rooms by means of refrigeration. That was the enterprise of the late Mr. Tata, a Parsee millionaire, by whom he was consulted some years ago as to the best means of cooling rooms. It was decided that the most efficient effect would be produced by blowing air over brine coils, and diffusing the air in at the top of the rooms. One of the great difficulties, however, of applying that system to any extent was, that no person could stand a sudden reduction of more than 10° without suffering from pneumonia or similar complaints. It was not safe for people living in a hot climate like India to suddenly go into a temperature which was reduced more than ten degrees. He had a curious commission a few years ago to design an artificially refrigerated summer house for an Indian Rajah, which was to stand in his grounds and act as a place of refuge for him on hot days, one of the principal stipulations being that a cupboard should be installed in the summer-house in which he could keep liquid refreshment cooled to a suitable temperature. Reference had been made to morgues and the preparation of anti-toxin by the grinding of the dead bodies of microbes; but he thought the less he went into such details the better the audience would be pleased, and he therefore passed over those matters lightly. Nevertheless, the use of refrigeration had had amazing results in that connection, and he would be pleased to supply any information on those topics to anybody who particularly hungered for it. Mr. Arthur Williams had referred to the cooling of photographic-plate rooms, and stated that he found snow on brine pipes perfectly satisfactory as an air filter. The reason why water was used to clean the air was that, when there was a stream of water falling down, every particle of air taken from the room and being blown by the fan had to pass through that water; whereas there were spaces between the coils, through which the air could pass without coming in contact with the snow. If the amount of snow on the pipes was very large, the area through which the air could pass was considerably reduced, and it had been found that the atmosphere most free from dust was obtained by blowing it through water; in addition there was the saving in latent heat if the moisture in the air was not frozen on coils. Mr. Arthur Williams also referred to the Chairman's invention for the de-frosting of meat. That was really another application of drying; in fact, he thought there was no doubt that it was the successful and novel method of drying air by freezing, which Sir Montague instituted in his de-frosting apparatus, and to which he drew attention in his patent, which first directed the attention of the industrial world to the great benefits which all sorts of processes could derive by drying with a low temperature in that way.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Hal Williams for his instructive and interesting paper, and the meeting terminated.

INEBRIETY AND INSANITY.

"I am satisfied that the majority of our insane inebriates have become alcoholics because of congenital defect or tendency to insanity, not insane as the result of alcoholism, and that the drunkenness which preceeded 'alcoholic insanity' was merely the herald —the only obvious sign—of incipient mental disorder." This sentence is taken from the report of the Inspector under the Inebriates' Acts, 1879 to 1900, a report that deserves the attention not only of magistrates and of others concerned with the administration of justice, but also of the Legislature.

Mr. Branthwaite's contention is that it is morally certain that many of the lunatics now in the asylums might have been prevented from becoming insane if they had been taken charge of when recovering from drunkenness, and properly treated earlier in their career. In the cases of insanity due to change in brain tissue the degeneration would not have occurred, and in those for which incipient brain disorder was apparently to blame, active development might not have supervened. Mr. Branthwaite asserts that mental incompetence stopping short of insanity holds a prominent position in the causation of habitual drunkenness, and that complete irresponsibility for drunkenness may result therefrom. The refractory persons sent to reformatories as inebriates are mentally unsound first and inebriates afterwards. "The physical demand for something to moderate restlessness and excitability, or cause temporary oblivion during the earlier stages of an attack of mad passion, accounts for their resort to alcohol. During an attack the same ungoverned impulse which prompts them to the committal of other unreasonable actions prompts them to drink madly regardless of results." If Mr. Braithwaite is right, the only possibility of an orderly life for such persons is total abstinence from liquor, a fact they have not the power to grasp, or if they do grasp it there are so many moments in their lives when insane impulse takes the place of thought and deliberation, that it is hopeless to expect improvement in conduct

unless preceded by improvement in mental condition. Such cases are almost hopeless when viewed in the light of possible reformability. Mr. Branthwaite says it is hardly realised how potent ordinary disease and ill health are in the making of inebriates. Impaired vitality lessens resisting power, and predisposition assumes unchecked sway.

Mr. Branthwaite gives many cases to support his thesis that very often habitual drunkenness may be due to abnormal physical conditions. For example: —Recently five women have been admitted to the reformatory suffering from advanced abdominal cancer. In each case experts to whom they were submitted for examination reported that the disease was of long standing, and, consequently, too far advanced for operative interference. The drunken history of these women does not go back more than an average of about three years, prior to which four of them held good characters as hard-working women, and there was nothing seriously wrong with the conduct of the fifth. These women attributed their drinking habits to "nipping," for the relief of pain and to remove the "sinking feeling" of "indigestion." Mr. Branthwaite has no doubt whatever that their drunkenness may safely be attributed to the pain and exhaustion of developing disease.

A woman described before her accident "as steady and plodding" was kicked on the head by a horse. Details are wanting as to the exact nature of her injury, but she was "unconscious for a long time, and for weeks afterwards was under treatment." When she had recovered sufficiently to go about by herself, she commenced a life of drunkenness, which soon brought her to the police-court, and ultimately to a reformatory.

Mr. Branthwaite contends that in very many cases which are treated by magistrates as ordinary offences against the law, for which fine or imprisonment is the proper punishment, the objectionable habits complained of are in no sense due to an effort of will, to a determination to get drunk after sane deliberation, but really to an absence of power to exercise judgment at all, or to the dictates of a warped judgment. Their actions are ungovernable because the mechanism provided for the purpose of government is out of gear, because the brain is so undeveloped, disordered, or poisoned as to be incapable of exercising anything beyond a mere semblance of control. Regarded as a remedy for habitual drunkenness, oft-repeated confinement in prison is, in Mr. Branthwaite's opinion, indefensible. "That such a course should ever have become established is evidence of old-time ignorance concerning the psychological and neurotic aspects of the question; that it should have grown to its present extent is partly due to the hard and fast doctrine of sin and punishment; that in face of all evidence of the uselessness, it still persists, is simply inexplainable. Its futility has been accepted for years past, and yet at the end of a century of exceptional progress, and at the beginning of another of greater promise, it still seems barely possible to look at a drunkard in a police-court without giving him "Five shillings or seven days."

Mr. Branthwaite's contention is that the repeated imprisonment of habitual inebriates not only neither cures nor deters, but makes the offenders worse than ever. Those who have had long experience in the treatment of drunkards, know that it is necessary to give drugs and careful medical attention during the period of recovery from a drinking bout, to prevent the shock and harmful effects of a sudden discontinuance of liquor. "When hundreds of drunkards are sent to prison every week, individual attention to the extent necessary to avoid shock is impossible. It is, therefore, more than probable that repeated arrest, with its sudden discontinuance of liquor, will in the end produce permanent injury to brain and nervous organisation. If the prison system neither cures nor deters, does it afford reasonable protection to the community? In Mr. Branthwaite's opinion is does not. The intervals of dangerous liberty are too frequent for any public advantage to accrue. Unless therefore we are prepared to admit that the process of imprisonment for short periods is solely one of retaliative vengeance, it is useless, and because useless, an absolute waste of public money. If this be a correct diagnosis, then many insane inmates have been punished for years as sane criminals, being thrown into prison with monotonous regularity simply because their ravings were intensified by drink or mistaken for drunken disorder, and many others definitely imbecile and epileptic have met with similar treatment merely because drunkenness happened to be the most prominent symptom, and because the exact condition was so masked by inebriate habits as to be impossible of diagnosis by non-medical administrators of justice.

What then is the remedy suggested? In Mr. Branthwaite's opinion the main points which call for attention and amendment are the delayed committal of inebriates to reformatories, and the unsatisfactory nature of their previous treatment. It is heart-breaking, he says, to watch the admission of one case after another, each bearing the stamp of hopeless irreformability, and know that the result is a foregone conclusion—because no earlier effort has been made to reform. Mr. Branthwaite asks whether prison cannot be avoided altogether in the majority of cases, and he refers with approval to the suggestion of a well known stipendiary magistrate. Instead of holding the threat of prison over habitual drunkards, and inflicting fines which sooner or later mean prison, he suggests that the possibility of being sent to reformatories should be kept before them from the first, and that each conviction as it occurs should be looked upon as a step towards that end. The first conviction under such a scheme would mean a discharge with a caution; the second would be similarly treated, with the additional information to the prisoner that one step nearer committal had been reached; the third conviction, bound over to be of good behaviour; and the fourth, within the year, committal to a reformatory. Such a

course would provide the managers of reformatories with better material, would give the prisoner a real chance of reformation, and would be economic in every sense of the word. The routine of a prison is no more suited to the needs of an habitual drunkard than it is suited to the treatment of any other form of mental unsoundness. He requires care and control on looser lines, something more individually suited to his temperament than the cellular solitude to which he is subjected during short sentences.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admtralty in December, 1906 :—
